| 31:0  | <b>TscAux: auxiliary time stamp counter data.</b> Read-write. It is expected that this is initialized by privileged software to a meaningful value, such as a processor ID. This value is returned in the RDTSCP instruction. |

#### MSRC000\_0104 Time Stamp Counter Ratio (TscRateMsr)

[MSRC000\\_0104 \[Time Stamp Counter Ratio \(TscRateMsr\)\]](#) allows the hypervisor to control the guest's view of the Time Stamp Counter. It provides a multiplier that scales the value returned when [MSR0000\\_0010\[TSC\]](#) and [MSR0000\\_00E7\[MPERF\]](#) are read by a guest running under virtualization. This allows the hypervisor to provide a consistent TSC and MPERF rate for a guest process when moving that process between cores that have a differing P0 rate. The TSC Ratio MSR does not affect the value read from the TSC and MPERF MSRs when read when in host mode or when virtualization is not being used or when accessed by code executed in system management mode (SMM) unless the SMM code is executed within a guest container. The TSC Ratio value does not affect the rate of the underlying TSC and MPERF counters, or the value that gets written to the TSC and MPERF MSRs counters on a write by either the host or the guest. The TSC Ratio MSR contains a fixed-point number in 8.32 format, which is 8 bits of integer and 32 bits of fraction. This number is the ratio of the desired P0 frequency to the P0 frequency of the core. The reset value of the TSC Ratio MSR is 1.0, which results in a guest frequency matches the core P0 frequency.

| Bits  | Description                                                                                                                                       |

| 18      | <b>Edge: edge detect.</b> Read-write. 0=Level detect. 1=Edge detect. The edge count mode increments the counter when a transition happens on the monitored event. If the event selected is changed without disabling the counter, an extra edge is falsely detected when the first event is a static 0 and the second event is a static one. To avoid this false edge detection, disable the counter when changing the event and then enable the counter with a second MSR write.                                                                                                                                                                                                                                                                                                                             |      |            |     |                                                                                                                                                         |         |                                                                                                                                                                              |  |                                                                                                                                                           |         |           |

| 15:8        | <b>UnitMask: event qualification.</b> Read-write. Each UnitMask bit further specifies or qualifies the event specified by EventSelect. All events selected by UnitMask are simultaneously monitored. Unless otherwise stated, the UnitMask values shown may be combined (logically ORed) to select any desired combination of the sub-events for a given event. In some cases, certain combinations can result in misleading counts, or the UnitMask value is an ordinal rather than a bit mask. These situations are described where applicable, or should be obvious from the event descriptions. For events where no UnitMask table is shown, the UnitMask is not applicable and may be set to zeros.                                                                                                                                                                                                                                                       |             |                   |      |    |      |    |      |    |      |    |      |    |      |    |      |    |      |           |

### **MSRC001\_00[07:04] Performance Event Counter (PERF\_CTR[3:0])**

The core provides four 48-bit performance counters. Each counter can monitor a different event specified by [MSRC001\\_00\[03:00\] \[Performance Event Select \(PERF\\_CTL\[3:0\]\)\]](#). The accuracy of the counters is not ensured.

Performance counters are used to count specific processor events, such as data-cache misses, or the duration of events, such as the number of clocks it takes to return data from memory after a cache miss. During event counting, the processor increments the counter when it detects an occurrence of the event. During duration measurement, the processor counts the number of processor clocks it takes to complete an event. Each performance counter can be used to count one event, or measure the duration of one event at a time.

In addition to the RDMSR instruction, the PERF\_CNT[3:0] registers can be read using a special read performance-monitoring counter instruction, RDPMC. The RDPMC instruction loads the contents of the PERF\_CTR[3:0] register specified by the ECX register, into the EDX register and the EAX register.

Writing the performance counters can be useful if there is an intention for software to count a specific number of events, and then trigger an interrupt when that count is reached. An interrupt can be triggered when a performance counter overflows. Software should use the WRMSR instruction to load the count as a two's-complement negative number into the performance counter. This causes the counter to overflow after counting the appropriate number of times.

The performance counters are not assured of producing identical measurements each time they are used to measure a particular instruction sequence, and they should not be used to take measurements of very small instruction sequences. The RDPMC instruction is not serializing, and it can be executed out-of-order with respect to other instructions around it. Even when bound by serializing instructions, the system environment at

the time the instruction is executed can cause events to be counted before the counter value is loaded into EDX:EAX.

Table 217: [Register Mapping](#) for [MSRC001\\_00\[07:04\]](#)

| Register     | Function  |
|--------------|-----------|
| MSRC001_0004 | Counter 0 |
| MSRC001_0005 | Counter 1 |
| MSRC001_0006 | Counter 2 |
| MSRC001_0007 | Counter 3 |

| Bits  | Description                                                                                                  |
|-------|--------------------------------------------------------------------------------------------------------------|
| 63:48 | RAZ.                                                                                                         |
| 47:0  | <b>CTR: performance counter value.</b> Read-write. Reset: 0. Returns the current value of the event counter. |

| 27    | Reserved. Read-write.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| 26    | <b>EffFreqCntMwait: effective frequency counting during mwait.</b> Read-write. Reset: 0. Specifies whether <a href="#">MSR0000_00E7 [Max Performance Frequency Clock Count (MPERF)]</a> and <a href="#">MSR0000_00E8 [Actual Performance Frequency Clock Count (APERF)]</a> increment while the core is in the monitor event pending state (when the mwait instruction has been executed). 0=The registers do not increment. 1=The registers increment. See <a href="#">2.5.3.3 [Effective Frequency]</a> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| 25    | <b>CpbDis: core performance boost disable.</b> Read-write. Reset: 0. Specifies whether core performance boost is requested to be enabled or disabled. 0=CPB is requested to be enabled. 1=CPB is disabled. See <a href="#">2.5.9 [Application Power Management (APM)]</a> . If this bit is set on any core, then CPB is disabled on all cores in the processor. If core performance boost is disabled while a core is in a boosted P-state, the core will automatically transition to the highest performance non-boosted P-state. A write to <a href="#">MSRC001_0015[CpbDis]</a> is aliased to <a href="#">D18F4x114[CpbDis]</a> . A read of <a href="#">MSRC001_0015[CpbDis]</a> returns the last value written to <a href="#">MSRC001_0015[CpbDis]</a> . When <a href="#">D18F4x114[CpbDis]</a> is set on any core, the NB initiates a P-state limit on all cores. The P-state limit is set to the highest performance non-boosted P-state. See <a href="#">2.5.5.1.6 [Modification of P-state Requests and Visibility]</a> . |
| 24    | <b>TscFreqSel: TSC frequency select.</b> Read-only. Reset: 1. 1=The TSC increments at the P0 frequency. This field uses software P-state numbering. | 18    | <p><b>McStatusWrEn: machine check status write enable.</b> Read-write. Reset: 0. McStatusWrEn can be used to debug machine check exception and interrupt handlers. See 2.14.3 [Error Injection and Simulation]. See 2.14.1 [Machine Check Architecture].</p> <ul style="list-style-type: none"> <li>• 1=Writes by software to MCi_STATUS (see 2.14.1 [Machine Check Architecture]) do not cause general protection faults; such writes update all implemented bits in these registers.</li> <li>• 0=MCi_STATUS registers are readable; writing a non-zero pattern to these registers causes a general protection fault.</li> <li>• The MCi_STATUS registers are: MSR0000_0401, MSR0000_0405, MSR0000_0409, MSR0000_040D, MSR0000_0411, MSR0000_0415. McStatusWrEn does not affect the writability of MSR0000_0001; MSR0000_0001 is always writable.</li> </ul> |
| 17    | <p><b>Wrap32Dis: 32-bit address wrap disable.</b> Read-write. Reset: 0. 1=Disable 32-bit address wrapping. Software can use Wrap32Dis to access physical memory above 4 Gbytes without switching into 64-bit mode. To do so, software should write a greater-than 4 Gbyte address to MSRC000_0100 [FS Base (FS_BASE)] and MSRC000_0101 [GS Base (GS_BASE)]. Then it would address <math>\pm 2</math> Gbytes from one of those bases using normal memory reference instructions with a FS or GS override prefix. However, the INVLPG, FST, and SSE store instructions generate 32-bit addresses in legacy mode, regardless of the state of Wrap32Dis.</p>                                                                                                                                                                                                       |

Operating systems that maintain page tables in any other memory type must set the TlbCacheDis bit to insure proper operation. <ul style="list-style-type: none"> <li>• TlbCacheDis does not override the memory type specified by the SMM ASeg and TSeg memory regions. See <a href="#">2.4.8.2.7 [The Protected ASeg and TSeg Areas]</a>.</li> <li>• Non-SMM mode page table walks page fault using the reserved error code if directed to the ASeg or TSeg memory regions.</li> </ul> |
| 1 | Reserved. Read-write.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| 0 | <b>SmmLock: SMM code lock.</b> Read; write-1-only. Reset: 0. SBIOS: 1. 1=SMM code in the ASeg and TSeg range and the SMM registers are read-only and SMI interrupts are not intercepted in SVM. See <a href="#">2.4.8.2.9 [Locking SMM]</a> .                                                                                                                                                                                                                                                                                                                                                                                                                                |

### MSRC001\_00[18,16] IO Range Base (IORR\_BASE[1:0])

Reset: 0000\_0000\_0000\_0000h. MSRC001\_0016 and MSRC001\_0017 combine to specify the first IORR range and MSRC001\_0018 and MSRC001\_0019 combine to specify the second IORR range. A core access, with address CPUAddr, is determined to be within IORR address range if the following equation is true: CPUAddr[39:12] & PhyMask[39:12] == PhyBase[39:12] & PhyMask[39:12].

BIOS can use the IORRs to create an IO hole within a range of addresses that would normally be mapped to DRAM. It can also use the IORRs to re-assert a DRAM destination for a range of addresses that fall within a bigger IO hole that overlays DRAM. See [2.4.6.1.2 \[Determining The Access Destination for Core Accesses\]](#).

| 45 | <b>DisUsSysMgtReqToNcHt: disable upstream system management request to link.</b> Reset: 0. 1=Disables downstream reflection of upstream STPCLK and x86 legacy input system management commands (in order to work around potential deadlock scenarios related to reflection regions).                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| 36 | <b>DisDatMsk: disable data mask.</b> Reset: 0. BIOS: IF ( <a href="#">DataMaskMbType!=1</a> ) THEN 1 ELSE 0 ENDIF. 1=Disables DRAM data masking function; all write requests that are less than one cacheline, a DRAM read is performed before writing the data. Data masking is supported in ECC mode; the NB performs a minimum write size of 16B. Note that when this feature is disabled, the DCT will drive the DM pins low during MCT writes to x8 DIMMs. See also TriDM.                                                                                                                                                                                                                                                                                                                                                                           |
| 31 | <b>DisCohLdtCfg: disable coherent link configuration accesses.</b> Reset: 0. 1=Disables automatic routing of PCI configuration accesses to the processor configuration registers; PCI configuration space accesses which fall within the hard-coded range reserved for processor configuration-space registers are instead routed to the IO link specified by <a href="#">D18F1x[1DC:1D0,EC:E0]</a> [ <a href="#">Configuration Map</a> ]. This can be used to effectively hide the configuration registers from software. It can also be used to provide a means for an external chip to route processor configuration accesses according to a scheme other than the hard-coded version. When used, this bit needs to be set on all processors in a system. PCI configuration accesses should not be generated if this bit is not set on all processors. |
| 27 | <b>DisDramScrub.</b> Reset: 0. 1=Disable DRAM ECC scrubbing; this overrides the settings in <a href="#">D18F3x58</a> [ <a href="#">Scrub Rate Control</a> ], <a href="#">D18F3x5C</a> [ <a href="#">DRAM Scrub Address Low</a> ].                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| 18 | <b>DisCstateBoostBlockPstateUp.</b> Read-write. Reset: 0. BIOS: <a href="#">D18F5x88</a> [ <a href="#">EnCstateBoostBlockCC6Exit</a> ]. 1=Allow cores that are waking up out of a non-C0 C-state to transition to the last requested Pstate without having to wait for cores in the boosted P-state to transition out of the boosted P-state.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |

### MSRC001\_0022 Machine Check Exception Redirection

Reset: 0000\_0000\_0000\_0000h. This register can be used to redirect machine check exceptions (MCEs) to SMIs or vectored interrupts. If both RedirSmiEn and RedirVecEn are set, then undefined behavior results.

| Bits  | Description                                                                                                                                                                                                                             |

### MSRC001\_00[35:30] Processor Name String

Reset: 0000\_0000\_0000\_0000h. BIOS: [Table 219](#). These registers hold the CPUID name string in ASCII. The state of these registers are returned by CPUID instructions, [CPUID Fn8000\\_000\[4:2\]\\_E\[D,C,B,A\]X](#). BIOS should set these registers to the product name for the processor as provided by AMD. Each register contains a block of 8 ASCII characters; the least byte corresponds to the first ASCII character of the block; the most-significant byte corresponds to the last character of the block. MSRC001\_0030 contains the first block of

the name string; MSRC001\_0035 contains the last block of the name string.

Table 218: [Register Mapping](#) for [MSRC001\\_00\[35:30\]](#)

| Register     | Function         |
|--------------|------------------|
| MSRC001_0030 | Characters 7-0   |
| MSRC001_0031 | Characters 15-8  |
| MSRC001_0032 | Characters 23-16 |
| MSRC001_0033 | Characters 31-24 |
| MSRC001_0034 | Characters 39-32 |
| MSRC001_0035 | Characters 47-40 |

See [D18F5x194](#) for the access method to [D18F5x198\\_x\[B:0\]](#).

Table 219: [BIOS Recommendations](#) for [MSRC001\\_00\[35:30\]](#)

| Register     | BIOS                         |
|--------------|------------------------------|
| MSRC001_0030 | {D18F5x198_x1, D18F5x198_x0} |
| MSRC001_0031 | {D18F5x198_x3, D18F5x198_x2} |
| MSRC001_0032 | {D18F5x198_x5, D18F5x198_x4} |
| MSRC001_0033 | {D18F5x198_x7, D18F5x198_x6} |
| MSRC001_0034 | {D18F5x198_x9, D18F5x198_x8} |
| MSRC001_0035 | {D18F5x198_xB, D18F5x198_xA} |

| Bits | Description                        |
|------|------------------------------------|
| 63:0 | <b>CpuNameString</b> . Read-write. |

### MSRC001\_003E Hardware Thermal Control (HTC)

Only one of these registers exists in multi-core devices; see [3.1.1 \[Northbridge MSRs In Multi-Core Products\]](#). Uses hardware P-state numbering. See [2.5.3.1.1.2 \[Hardware P-state Numbering\]](#).

| Bits  | Description                                                                                                                                                                                                                                                    |

### **MSRC001\_00[53:50] IO Trap (SMI\_ON\_IO\_TRAP\_[3:0])**

Reset: 0000\_0000\_0000\_0000h.

[MSRC001\\_00\[53:50\]](#) and [MSRC001\\_0054](#) provide a mechanism for executing the SMI handler if a an access to one of the specified addresses is detected. Access address and access type checking is performed before IO instruction execution. If the access address and access type match one of the specified IO address and access types, then: (1) the IO instruction is not executed; (2) any breakpoint, other than the single-step breakpoint, set on the IO instruction is not taken (the single-step breakpoint is taken after resuming from SMM); and (3) the SMI-trigger IO cycle specified by [MSRC001\\_0056](#). The status is stored in [SMMFEC4\[IoTrapSts\]](#).

IO-space configuration accesses are special IO accesses. An IO access is defined as an IO-space configuration access when IO instruction address bits[31:0] are CFCh, CFDh, CFEh, or CFFh when IO-space configuration is enabled ([IOCF8\[ConfigEn\]](#)). The access address for a configuration space access is the current value of [IOCF8\[BusNo, Device, Function, RegNo\]](#). The access address for an IO access that is not a configuration access is equivalent to the IO instruction address, bits[31:0].

The access address is compared with SmiAddr, and the instruction access type is compared with the enabled access types defined by ConfigSMI, SmiOnRdEn, and SmiOnWrEn. Access address bits[23:0] can be masked with SmiMask.

IO and configuration space trapping to SMI applies only to single IO instructions; it does not apply to string and REP IO instructions.

The conditional GP fault described by [MSRC001\\_0015\[IoCfgGpFault\]](#) takes priority over this trap.

Table 220: [Register Mapping](#) for [MSRC001\\_00\[53:50\]](#)

| Register     | Function |
|--------------|----------|
| MSRC001_0050 | Range 0  |

### MSRC001\_0056 SMI Trigger IO Cycle

[Not-same-for-all](#); S3-check-exclude. Reset: 0000\_0000\_0000\_0000h. See [2.4.8.2.3 \[SMI Sources And Delivery\]](#). This register specifies an IO cycle that may be generated when a local SMI trigger event occurs. If IoCycleEn is set and there is a local SMI trigger event, then the IO cycle generated is a byte read or write, based on IoRd, to address IoPortAddress. If the cycle is a write, then IoData contains the data written. If the cycle is a read, the value read is discarded. If IoCycleEn is clear and a local SMI trigger event occurs, then undefined behavior results.

### MSRC001\_0060 BIST Results

Read; GP-write. Reset: 0000\_0000\_xxxx\_xxxxh. This register provides BIST results after each reset. The results provided here are identical to the values provided in EAX. If (MSRC001\_0060[29:0]=0000\_0000h) then no BIST failures were detected. Bits[31:0] below provide the BIST test name; 1=A failure was detected on that test.

**MSRC001\_0061 P-state Current Limit**

Read; GP-write; updated-by-hardware. See [2.5.3 \[CPU Power Management\]](#).

| Bits | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
|------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 63:7 | RAZ.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| 6:4  | <b>PstateMaxVal: P-state maximum value.</b> Specifies the lowest-performance non-boosted P-state (highest non-boosted value) allowed. Attempts to change <a href="#">MSRC001_0062[PstateCmd]</a> to a lower-performance P-state (higher value) are clipped to the value of this field. This clipping is enforced by microcode, see <a href="#">MSRC001_0062[PstateCmd]</a> . This field uses software P-state numbering. See <a href="#">2.5.3.1.1.1 [Software P-state Numbering]</a> . The state of this field is controlled through <a href="#">D18F3xDC[HwPstateMaxVal]</a> .                                                                                                                                                                                                                                                                               |
| 3    | RAZ.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| 2:0  | <b>CurPstateLimit: current P-state limit.</b> Specifies the highest-performance non-boosted P-state (lowest value) allowed. CurPstateLimit is always bounded by <a href="#">MSRC001_0061[PstateMaxVal]</a> . Attempts to change the CurPstateLimit to a value greater (lower performance) than <a href="#">MSRC001_0061[PstateMaxVal]</a> leaves CurPstateLimit unchanged. This field uses software P-state numbering. See <a href="#">MSRC001_0071[CurPstateLimit]</a> and <a href="#">2.5.3.1.1.1 [Software P-state Numbering]</a> .<br>$\text{CurPstateLimit} = \text{Max} \{ (\text{D18F3x64}[\text{HtcPstateLimit}] - \text{D18F4x15C}[\text{NumBoostStates}]) \text{ if } \text{D18F3x64}[\text{HtcAct}]=1, (\text{D18F3x68}[\text{SwPstateLimit}] - \text{D18F4x15C}[\text{NumBoostStates}]) \text{ if } \text{D18F3x68}[\text{SwPstateLimitEn}]=1 \}.$ |

**MSRC001\_0062 P-state Control**

| Bits | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |

| 63:3 | MBZ.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| 2:0  | <b>PstateCmd: P-state change command.</b> Read-write; <b>Not-same-for-all</b> . Cold reset value varies by product; after a warm reset, value initializes to the P-state the core was in prior to the reset; copied from <a href="#">MSRC001_0071[CurPstate]</a> after all resets. Writes to this field cause the core to change to the indicated non-boosted P-state number, specified by <a href="#">MSRC001_00[6B:64]</a> . 0=P0, 1=P1, etc. P-state limits are applied to any P-state requests made through this register. Reads from this field return the last written value, regardless of whether any limits are applied. This field uses software P-state numbering. See <a href="#">2.5.3 [CPU Power Management]</a> and <a href="#">2.5.3.1.1.1 [Software P-state Numbering]</a> . Writes to this field that do not change <a href="#">MSRC001_0063[CurPstate]</a> cause VID changes but do not cause COF updates if the corresponding <a href="#">MSRC001_00[6B:64]</a> have changed. |

**MSRC001\_0063 P-state Status**

Read; GP-write; Updated-by-hardware.

| 2:0  | <b>CurPstate: current P-state.</b> Cold reset: <a href="#">MSRC001_0071</a> [CurPstate]. This field provides the frequency component of the current non-boosted P-state of the core (regardless of the source of the P-state change, including <a href="#">MSRC001_0062</a> [PstateCmd] and <a href="#">D18F3xC4</a> [SBI P-state Limit]; see <a href="#">2.5.3.1.5 [Core P-state Transition Behavior]</a> for information on how these interact). 0=P0, 1=P1, etc. The value of this field is updated when the COF transitions to a new value associated with a P-state. This field uses software P-state numbering. See <a href="#">2.5.3 [CPU Power Management]</a> and <a href="#">2.5.3.1.1 [Software P-state Numbering]</a> . This field is transported from <a href="#">D18F3xC8</a> after the value is modified as specified by <a href="#">2.5.5.1.6 [Modification of P-state Requests and Visibility]</a> . |

### MSRC001\_00[6B:64] P-state [7:0]

**Per-node.** Cold reset: [D18F4x1](#)[FC:E0]. Each of these registers specify the frequency and voltage associated with each of the core P-states.

Table 221: [Register Mapping](#) for [MSRC001\\_00](#)[6B:64]

| Register     | Function  |
|--------------|-----------|
| MSRC001_0064 | P-state 0 |
| MSRC001_0065 | P-state 1 |
| MSRC001_0066 | P-state 2 |
| MSRC001_0067 | P-state 3 |
| MSRC001_0068 | P-state 4 |
| MSRC001_0069 | P-state 5 |
| MSRC001_006A | P-state 6 |
| MSRC001_006B | P-state 7 |

The CpuVid field in these registers is required to be programmed to the same value in all cores of a processor, but are allowed to be different between processors in a multi-processor system. All other fields in these registers are required to be programmed to the same value in each core of the coherent fabric. See [2.5.3 \[CPU Power Management\]](#).

When [D18F4x15C](#)[BoostLock]=1, [MSRC001\\_00](#)[6B:64][CpuVid, CpuDid, CpuFid] have special write requirements associated with them. These requirements are enforced by the Northbridge prior to writing [D18F4x1](#)[FC:E0]. Microcode transports this register to [D18F4x1](#)[FC:E0].

Table 222: P-state Definitions

| Term    | Definition                                                                                                                                                            |
|---------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| CoreCOF | Core current operating frequency in MHz. $\text{CoreCOF} = 100 * (\text{MSRC001\_00}[6B:64][\text{CpuFid}] + 10h) / (2^{\text{MSRC001\_00}[6B:64][\text{CpuDid}]})$ . |

| Bits          | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |               |                    |     |                                    |     |                                      |     |                                       |     |          |

If this bit is set in any given P-state register, then it must also be set in all enabled lower performance P-state registers as well. Equivalent P-states in each core must program this bit to the same value. See <a href="#">2.5.4.1 [NB P-states]</a> and <a href="#">D18F5x170[NbPstateThreshold, NbPstateLo, NbPstateHi]</a> . Alias of <a href="#">D18F4x1[FC:E0][NbPstate]</a> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |               |                    |     |                                    |     |                                      |     |                                       |     |          |

| 5:0   | <p><b>CpuFid[5:0]: core frequency ID.</b> Read-write. Except as required by 2.5.3.1.7 [Processor-Systemboard Power Delivery Compatibility Check], software should not modify this field. Specifies the core frequency multiplier. The core COF is a function of CpuFid and CpuDid, and defined by CoreCOF. CpuFid and CpuDid must be programmed to the requirements specified in MSRC001_0071[MaxCpuCof] and D18F3xD4[MaxSwPstateCpuCof].</p> <p>Writes to a non-boosted P-state with frequencies greater than D18F3xD4[MaxSwPstateCpuCof] are ignored. Writes to a boosted P-state with frequencies greater than MSRC001_0071[MaxCpuCof] are ignored. If D18F4x15C[BoostLock]=1, then CpuDid for boosted P-states can only be written with values that are greater than or equal to the reset value in CpuDid. If D18F4x15C[BoostLock]=1, then CpuFid for boosted P-states can only be written with values that are less than or equal to the reset value in CpuFid. See 2.5.3.1.5 [Core P-state Transition Behavior].</p> <p>Alias of D18F4x1[FC:E0][CpuFid].</p> |      |             |    |             |    |             |    |             |    |             |    |              |       |          |

### MSRC001\_0070 COFVID Control

Cold reset: Product-specific. There is one register implemented for each core. This register includes several fields that are identical to MSRC001\_00[6B:64]. It is controlled by hardware for P-state transitions. It may also be used by software to directly control the current COF or VID. Alias of D18F3xC0.

Accesses to this register that result in invalid COFs or VIDs are ignored. See 2.5.3 [CPU Power Management].

| Bits  | Description                                                                                                                                                                                                                                                                                |

| 54:49 | <b>MaxCpuCof: maximum core COF.</b> Cold reset: Fuse[MaxCpuCof]. Specifies the maximum CPU COF supported by the processor. The maximum frequency is 100 MHz * MaxCpuCof, if MaxCpuCof is greater than zero; if MaxCpuCof = 00h, then there is no frequency limit. Any attempt to change a CPU COF to a frequency greater than specified by this field is ignored. Processors that support core performance boost must fuse this field to the maximum boosted P-state frequency or higher.                                                                                                                                                                                                                                                                                                                                                                                                                                                     |

| 34:32 | <b>StartupPstate: startup P-state number.</b> Cold reset: Fuse[StartupPstate]. Specifies the cold reset VID, FID and DID for the core based on the P-state number selected. StartupPstate uses hardware P-state numbering. See <a href="#">MSRC001_00[6B:64]</a> and <a href="#">2.5.3.1.1.2 [Hardware P-state Numbering]</a> . If <a href="#">D18F3xA0[CofVidProg]=0</a> , then the state of this field is ignored and the VID, FID and DID are applied to the core as specified by that bit. Hardware verifies that <a href="#">MSRC001_00[6B:64][CpuVid, CpuFid, CpuDid]</a> for the P-state pointed to by StartupPstate are programmed as specified by <a href="#">MSRC001_0071[MaxCpuCof]</a> . Hardware does not verify that PstateEn is set. See <a href="#">2.5.3.1.5 [Core P-state Transition Behavior]</a> . |
| 31:24 | <b>CurNbVid[7:0]: current NB VID.</b> Read-only; updated-by-hardware. Cold reset: Fuse[NbVid[Fuse[StartupNbPstate]]][7:0]]. This field specifies the current VDDNB voltage. <a href="#">MSRC001_0071[CurNbVid[7:0]]</a> is an alias of <a href="#">D18F5x174[CurNbVid[7:0]]</a> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| 23    | <b>NbPstateDis: NB P-states disabled.</b> Value: <a href="#">D18F5x174[NbPstateDis]</a> . <a href="#">MSRC001_0071[NbPstateDis]</a> is an alias of <a href="#">D18F5x174[NbPstateDis]</a> . 0=NB P-state frequency and voltage changes are supported. See <a href="#">D18F5x170[SwNbPstateLoDis, NbPstateDisOnP0]</a> . 1=NB P-state frequency and voltage changes are disabled.                                                                                                                                                                                                                                                                                                                                                                                                                                       |

| 15:0  | <b>CstateAddr: C-state address.</b> Read-write. Specifies the IO addresses trapped by the core for C-state entry requests. A value of 0 in this field specifies that the core does not trap any IO addresses for C-state entry. Writing values greater than FFF8h into this field result in undefined behavior. All other values cause the core to trap IO addresses CstateAddr through CstateAddr+7. See <a href="#">2.5.3.2.2 [C-state Request Interface]</a> , <a href="#">D18F4x11[C:8]</a> , and <a href="#">D18F4x11C</a> . |

**MSRC001\_0074 CPU Watchdog Timer (CpuWdtCfg)**

Read-write; [Same-for-all](#). Reset: 0000\_0000\_0000\_0000h.

The CPU watchdog timer (WDT) is implemented as a counter that counts out the time periods specified. The counter starts counting when CpuWdtEn is set. The counter does not count during halt or stop-grant. It restarts the count each time an operation of an instruction completes. If no operation completes by the specified time period, then a machine check error may be recorded if enabled (see [MSR0000\\_0414](#) through [MSR0000\\_0417](#)). If a watchdog timer error overflow occurs ([MSR0000\\_0415](#)[Overflow]), a sync flood can be generated if enabled in [D18F3x180](#)[SyncFloodOnCpuLeakErr].

The CPU watchdog timer must be set higher than the NB watchdog timer ([D18F3x44](#) [[MCA NB Configuration](#)]) in order to allow remote requests to complete. The CPU watchdog timer must be set the same for all CPUs in a system.

| Bits        | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |                       |                    |                       |         |      |         |     |                 |      |          |      |        |    |     |         |    |     |               |    |     |  |

| 6:3         | <b>CpuWdtCountSel: CPU watchdog timer count select.</b> CpuWdtCountSel and CpuWdtTimeBase together specify the time period required for the WDT to expire. The time period is ((the multiplier specified by CpuWdtCountSel) * (the time base specified by CpuWdtTimeBase)). The actual timeout period may be anywhere from zero to one increments less than the values specified, due to non-deterministic behavior. <table><tr><th><u>Bits</u></th><th><u>Multiplier</u></th><th><u>BitsMultiplier</u></th></tr><tr><td>0h</td><td>4095</td><td>6h63</td></tr><tr><td>1h</td><td>2047</td><td>7h31</td></tr><tr><td>2h</td><td>1023</td><td>8h8191</td></tr><tr><td>3h</td><td>511</td><td>9h16383</td></tr><tr><td>4h</td><td>255</td><td>Fh-AhReserved</td></tr><tr><td>5h</td><td>127</td><td></td></tr></table> | <u>Bits</u>           | <u>Multiplier</u>  | <u>BitsMultiplier</u> | 0h      | 4095 | 6h63    | 1h  | 2047            | 7h31 | 2h       | 1023 | 8h8191 | 3h | 511 | 9h16383 | 4h | 255 | Fh-AhReserved | 5h | 127 |  |

**MSRC001\_0111 SMM Base Address (SMM\_BASE)**

Reset: 0000\_0000\_0003\_0000h. This holds the base of the SMM memory region. The value of this register is stored in the save state on entry into SMM (see [2.4.8.2.5 \[SMM Save State\]](#)) and it is restored on returning from SMM. The 16-bit CS (code segment) selector is loaded with SmmBase[19:4] on entering SMM.

SmmBase[3:0] is required to be 0. The SMM base address can be changed in two ways:

- The SMM base address, at offset FF00h in the SMM state save area, may be changed by the SMI handler. The RSM instruction updates SmmBase with the new value.
- Normal WRMSR access to this register.

| Bits  | Description                                                                                                                                        |

| 63:32 | Reserved.                                                                                                                                          |
| 31:0  | <b>SmmBase.</b> IF <a href="#">MSRC001_0015[SmmLock]</a> THEN Read-only; <b>Not-same-for-all.</b> ELSE Read-write; <b>Not-same-for-all.</b> ENDIF. |

**MSRC001\_0112 SMM TSeg Base Address (SMMAddr)**

Reset: 0000\_0000\_0000\_0000h.

See [2.4.8.2 \[System Management Mode \(SMM\)\]](#) and [2.4.6.1 \[Memory Access to the Physical Address Space\]](#). See [MSRC001\\_0113](#) for more information about the ASeg and TSeg address ranges.

Each CPU access, directed at CPUAddr, is determined to be in the TSeg range if the following is true:

$\text{CPUAddr}[39:17] \& \text{TSegMask}[39:17] == \text{TSegBase}[39:17] \& \text{TSegMask}[39:17]$ .

For example, if TSeg spans 256 KB and starts at the 1 MB address. The [MSRC001\\_0112](#)[TSegBase] would be set to 0010\_0000h and the [MSRC001\\_0113](#)[TSegMask] to FFFC\_0000h (with zeros filling in for bits[16:0]). This results in a TSeg range from 0010\_0000 to 0013\_FFFFh.

| Bits  | Description                                                                                                                      |

| 39:17 | <b>TSegBase[39:17]: TSeg address range base.</b> IF <a href="#">MSRC001_0015</a> [SmmLock] THEN Read-only ELSE Read-write ENDIF. |
| 16:0  | Reserved.                                                                                                                        |

### **MSRC001\_0113 SMM TSeg Mask (SMMMMask)**

Reset: 0000\_0000\_0000\_0000h. See [2.4.8.2 \[System Management Mode \(SMM\)\]](#).

The ASeg address range is located at a fixed address from A0000h–BFFFFh. The TSeg range is located at a variable base (specified by [MSRC001\\_0112](#)[TSegBase]) with a variable size (specified by [MSRC001\\_0113](#)[TSegMask]). These ranges provide a safe location for SMM code and data that is not readily accessible by non-SMM applications. The SMI handler can be located in one of these two ranges, or it can be located outside these ranges. These ranges must never overlap each other.

This register specifies how accesses to the ASeg and TSeg address ranges are controlled as follows:

- If [A,T]Valid=1, then:
  - If in SMM, then:
    - If [A, T]Close=0, then the accesses are directed to DRAM with memory type as specified in [A, T]MTypeDram.
    - If [A, T]Close=1, then instruction accesses are directed to DRAM with memory type as specified in [A, T]MTypeDram and data accesses are directed at MMIO space and with attributes based on [A, T]MTypeIoWc.
  - If not in SMM, then the accesses are directed at MMIO space with attributes based on [A,T]MTypeIoWc.
- See [2.4.6.1.1 \[Determining Memory Type\]](#).

| Bits  | Description                                                                                                                                                                                                                                                                                             |

| 4     | <b>SvmeDisable: SVM disable.</b> See Lock for the access type of this field. Reset: 0. 1= <a href="#">MSRC000_0080</a> [SVME] is MBZ. 0= <a href="#">MSRC000_0080</a> [SVME] is read-write. Attempting to set this field when ( <a href="#">MSRC000_0080</a> [SVME]==1) causes a #GP fault, regardless of the state of Lock. See the APM2 section titled “Enabling SVM” for software use of this field.                                                                                                                                                                                                                             |
| 3     | <b>Lock: SVM lock.</b> Read-only; write-1-only; cleared-by-hardware. Reset: 0. See <a href="#">MSRC001_0118</a> [SvmLockKey] for the condition that causes hardware to clear this field. 1=SvmeDisable is read-only. 0=SvmeDisable is read-write.                                                                                                                                                                                                                                                                                                                                                                                   |
| 2     | <b>DisA20m: disable A20 masking.</b> Read-write; set-by-hardware. Reset: 0. 1=Disables A20 masking. This bit is set by hardware when the SKINIT instruction is executed.                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| 1     | <b>InterceptInit: intercept INIT.</b> Read-write; set-by-hardware. Reset: 0. This bit controls how INIT is delivered in host mode. This bit is set by hardware when the SKINIT instruction is executed. 0=INIT delivered normally. 1=INIT translated into a SX interrupt.                                                                                                                                                                                                                                                                                                                                                           |
| 0     | <b>DPD: debug port disable.</b> Read-write; set-by-hardware. Reset: 0. Set by hardware when the SKINIT instruction is executed. This bit controls if debug facilities such as JTAG and HDT have access to the processor state information. 1=HDT is disabled; SB-IAI is disabled; see <a href="#">D18F3x1E4</a> [SblaiDis]; functional chain fuses override disabled; RMW and Redundancy chain overrides (including cache size and core disable bits) are unaffected. 0=HDT may be enabled; SB-IAI may be enabled; see <a href="#">D18F3x1E4</a> [SwIaiDis]=0. Core DSM is automatically disabled when DPD transitions from 0 to 1. |

**MSRC001\_0115 IGNNE**

| Bits  | Description                                                                                                                          |
|-------|--------------------------------------------------------------------------------------------------------------------------------------|
| 63:32 | Reserved.                                                                                                                            |
| 31:1  | MBZ.                                                                                                                                 |
| 0     | <b>IGNNE: current IGNNE state.</b> Read-write. Reset: 0. This bit controls the current state of the processor internal IGNNE signal. |

**MSRC001\_0116 SMM Control (SMM\_CTL)**

IF (MSRC001\_0015[SmmLock]) THEN GP-read-write. ELSE GP-read; write-only. ENDIF.

The bits in this register are processed in the order of: SmmEnter, SmiCycle, SmmDismiss, RsmCycle and SmmExit. However, only the following combination of bits may be set in a single write (all other combinations result in undefined behavior):

- SmmEnter and SmiCycle.
- SmmEnter and SmmDismiss.
- SmmEnter, SmiCycle and SmmDismiss.
- SmmExit and RsmCycle.

Software is responsible for ensuring that SmmEnter and SmmExit operations are properly matched and are not nested.

| Bits | Description                                                          |
|------|----------------------------------------------------------------------|
| 63:5 | MBZ.                                                                 |
| 4    | <b>RsmCycle: send RSM special cycle.</b> 1=Send a RSM special cycle. |
| 3    | <b>SmmExit: exit SMM.</b> 1=Exit SMM.                                |
| 2    | <b>SmiCycle: send SMI special cycle.</b> 1=Send a SMI special cycle. |
| 1    | <b>SmmEnter: enter SMM.</b> 1=Enter SMM.                             |
| 0    | <b>SmmDismiss: clear SMI.</b> 1=Clear the SMI pending flag.          |

**MSRC001\_0117 Virtual Machine Host Save Physical Address (VM\_HSAVE\_PA)**

| Bits  | Description                                                                                                                                                                                                                                                                                      |
|-------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 63:40 | MBZ.                                                                                                                                                                                                                                                                                             |
| 39:12 | <b>VM_HSAVE_PA: physical address of host save area.</b> Read-write. Reset: 0. This register contains the physical address of a 4-KB region where VMRUN saves host state and where vm-exit restores host state from. Writing this register causes a #GP if (FF_FFFF_Fh>=VM_HSAVE_PA>=FD_0000_0h). |
| 11:0  | MBZ.                                                                                                                                                                                                                                                                                             |

**MSRC001\_0118 SVM Lock Key**

Reset: 0000\_0000\_0000\_0000h.

| Bits | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
|------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 63:0 | <b>SvmLockKey: SVM lock key.</b> RAZ; write. Writes to this register when <a href="#">MSRC001_0114[Lock]</a> ==0 modify SvmLockKey. If (( <a href="#">MSRC001_0114[Lock]</a> ==1) && (SvmLockKey!=0) && (The write value==The value stored in SvmLockKey)) for a write to this register then hardware updates <a href="#">MSRC001_0114[Lock]</a> =0. |------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 15:8 | <b>UnitMask: event qualification.</b> Read-write. Each UnitMask bit further specifies or qualifies the event specified by EventSelect. All events selected by UnitMask are simultaneously monitored. Unless otherwise stated, the UnitMask values shown may be combined (logically ORed) to select any desired combination of the sub-events for a given event. In some cases, certain combinations can result in misleading counts, or the UnitMask value is an ordinal rather than a bit mask. These situations are described where applicable, or should be obvious from the event descriptions. For events where no UnitMask table is shown, the UnitMask is <b>Unused</b> . |
| 7:0  | <b>EventSelect[7:0]: event select.</b> Read-write. This field, along with EventSelect[11:8] above, combine to form the 12-bit event select field, EventSelect[11:0]. EventSelect specifies the event or event duration in a processor unit to be counted by the corresponding PERF_CNT[3:0] register. The events are specified in section 3.23 [Core Performance Counter Events]. Some events are reserved; when a reserved event is selected, the results are undefined.                                                                                                                                                                                                        |

### MSRC001\_023[7,5,3,1] L2I Performance Event Counter (L2I\_PERF\_CTR[3:0])

Per-L2. See MSRC001\_023[6,4,2,0] [L2I Performance Event Select (L2I\_PERF\_CTL[3:0])].

Table 224: Register Mapping for MSRC001\_023[7,5,3,1]

| Register     | Function  |
|--------------|-----------|
| MSRC001_0231 | Counter 0 |
| MSRC001_0233 | Counter 1 |
| MSRC001_0235 | Counter 2 |
| MSRC001_0237 | Counter 3 |

| Bits  | Description                                                  |
|-------|--------------------------------------------------------------|
| 63:48 | RAZ.                                                         |
| 47:0  | <b>CTR: performance counter value.</b> Read-write. Reset: 0. |

### MSRC001\_024[6,4,2,0] Northbridge Performance Event Select (NB\_PERF\_CTL[3:0])

Per-node. See 2.6.1 [Performance Monitor Counters]. MSRC001\_024[6,4,2,0][31:0] is an alias of D18F5x[70,60,50,40]. MSRC001\_024[6,4,2,0][63:32] is an alias of D18F5x[74,64,54,44].

Table 225: Register Mapping for MSRC001\_024[6,4,2,0]

| Register     | Function  |
|--------------|-----------|
| MSRC001_0240 | Counter 0 |

**MSRC001\_102A Bus Unit Configuration 2 (BU\_CFG2)**

| Bits | Description                                                                                                                                                                                                                                                                                               |
|------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 15   | <b>CILinesToL2Dis</b> . Read-write. Reset: 1. BIOS: See <a href="#">2.3.3 [Using L2 Cache as General Storage During Boot]</a> . 1=Clean victims and clean forced victims are not sent to the L2. When this bit is set, clean DC evictions and all IC evictions are discarded by the BU (not sent to L2I). |
| 14:0 | Reserved.                                                                                                                                                                                                                                                                                                 |

**MSRC001\_1030 IBS Fetch Control (IbsFetchCtl)**

Reset: 0000\_0000\_0000\_0000h. See [2.6.2 \[Instruction Based Sampling \(IBS\)\]](#).

The IBS fetch sampling engine is described as follows:

- The periodic fetch counter is an internal 20-bit counter:
  - The periodic fetch counter [19:4] is set to IbsFetchCnt[19:4] and the periodic fetch counter [3:0] is set according to IbsRandEn when IbsFetchEn is changed from 0 to 1.
  - It increments for every fetch cycle that completes when IbsFetchEn=1 and IbsFetchVal=0.
    - The periodic fetch counter is undefined when IbsFetchEn=0 or IbsFetchVal=1.
  - When IbsFetchCnt[19:4] is read it returns the current value of the periodic fetch counter [19:4].
- When the periodic fetch counter reaches {IbsFetchMaxCnt[19:4],0h} and the selected instruction fetch completes or is aborted:
  - IbsFetchVal is set to 1.
    - Drivers can't assume that IbsFetchCnt[19:4] is 0 when IbsFetchVal==1.
  - The status of the operation is written to the IBS fetch registers (this register, [MSRC001\\_1031](#) and [MSRC001\\_1032](#)).
  - An interrupt is generated as specified by [MSRC001\\_103A](#). The interrupt service routine associated with this interrupt is responsible for saving the performance information stored in IBS execution registers.

| Bits  | Description                                                                                                                                                                                                                                                                                                                                 |

| 39:0  | <b>IbsFetchPhysAd: instruction fetch physical address.</b> Read-write; updated-by-hardware. Provides the physical address for the tagged instruction fetch. The lower 12 bits are not modified by address translation, so they are always the same as the linear address. This field contains valid data only if <a href="#">MSRC001_1030</a> [IbsPhyAddrValid] is asserted. |

### MSRC001\_1033 IBS Execution Control (IbsOpCtl)

Reset: 0000\_0000\_0000\_0000h. See [2.6.2 \[Instruction Based Sampling \(IBS\)\]](#).

The IBS execution sampling engine is described as follows for IbsOpCntCtl==1. If IbsOpCntCtl==1n then references to “periodic op counter” mean “periodic cycle counter”.

- The periodic op counter is an internal 27-bit counter:
  - It is set to IbsOpCurCnt[26:0] when IbsOpEn is changed from 0 to 1.
  - It increments every dispatched op when IbsOpEn=1 and IbsOpVal=0.
    - The periodic op counter is undefined when IbsOpEn=0 or IbsOpVal=1.
  - When IbsOpCurCnt[26:0] is read then it returns the current value of the periodic micro-op counter [26:0].
- When the periodic micro-op counter reaches IbsOpMaxCnt:
  - The next dispatched micro-op is tagged if IbsOpCntCtl==1. A valid op in the next dispatched line is tagged if IbsOpCntCtl==0. See IbsOpCntCtl.
  - The periodic micro-op counter [26:7]=0; [6:0] is randomized by hardware.
- The periodic micro-op counter is not modified when a tagged micro-op is flushed.
- When a tagged micro-op is retired:
  - IbsOpVal is set to 1.
    - Drivers can't assume that IbsOpCurCnt is 0 when IbsOpVal==1.
  - The status of the operation is written to the IBS execution registers (this register, [MSRC001\\_1034](#), [MSRC001\\_1035](#), [MSRC001\\_1036](#), [MSRC001\\_1037](#), [MSRC001\\_1038](#) and [MSRC001\\_1039](#)).
  - An interrupt is generated as specified by [MSRC001\\_103A](#). The interrupt service routine associated with this interrupt is responsible for saving the performance information stored in IBS execution registers.

| Bits  | Description                                                                                                                                                                                                                                                                                                                                                                                                                |

|       |                                                                                                                                                                                                                                                                                       |
|-------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31:16 | <b>IbsTagToRetCtr: micro-op tag to retire count.</b> Read-write; updated-by-hardware. Reset: 0. This field returns the number of cycles from when the micro-op was tagged to when the micro-op was retired. This field is equal to IbsCompToRetCtr when the tagged micro-op is a NOP. |
| 15:0  | <b>IbsCompToRetCtr: micro-op completion to retire count.</b> Read-write; updated-by-hardware. Reset: 0. This field returns the number of cycles from when the micro-op was completed to when the micro-op was retired.                                                                |

### MSRC001\_1036 IBS Op Data 2 (IbsOpData2)

Reset: 0000\_0000h. **MSRC001\_1036**[31:0] is an alias of **D18F3x1D0**. Northbridge data is only valid for load operations that miss both the L1 data cache and the L2 cache. If a load operation crosses a cache line boundary, the data returned in this register is the data for the access to the lower cache line.

| Bits  | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |      |             |    |                 |    |          |    |                                                       |    |                               |    |                           |    |          |    |          |    |                                                |

### MSRC001\_1037 IBS Op Data 3 (IbsOpData3)

Reset: 0000\_0000\_0000\_0000h. If a load or store operation crosses a 128-bit boundary, the data returned in this register is the data for the access to the data below the 128-bit boundary.

| Bits  | Description                                                                                                                                                                                         |

| 63:48 | <b>IbsTlbRefillLat: L1 DTLB refill latency.</b><br>Read-only. Value: 0.<br>The number of cycles from when a L1 DTLB refill is triggered by a tagged op to when the L1 DTLB fill has been completed. |

| 47:32 | <b>IbsDcMissLat: data cache miss latency.</b> Read-write; updated-by-hardware. Indicates the number of clock cycles from when a miss is detected in the data cache to when the data was delivered to the core. The value returned by this counter is not valid for data cache writes or prefetch instructions.                                                                                                                                                                             |      |             |    |                          |    |      |    |      |    |    |    |    |    |    |       |          |

### 3.23 Core Performance Counter Events

This section provides the performance counter events that may be selected through [MSRC001\\_00\[03:00\]\[EventSelect,UnitMask\]](#). See [MSRC001\\_00\[03:00\]](#) and [MSRC001\\_00\[07:04\] \[Performance Event Counter \(PERF\\_CTR\[3:0\]\)\]](#).

For L2I performance counter events see [2.6.1.2 \[L2I Performance Monitor Counters\]](#) and [3.24 \[L2I Performance Counter Events\]](#).

For NB performance counter events see [2.6.1.3 \[NB Performance Monitor Counters\]](#) and [3.25 \[NB Performance Counter Events\]](#).

#### 3.23.1 PMCx0[1F:00] Events (FP)

##### PMCx000 Dispatched FPU Operations

The number of operations (uops) dispatched to the FPU execution pipelines. This includes all operations done by x87, MMX™ and SSE instructions, including moves. This event is a speculative event. (See PMCx0CB). Since this event includes non-numeric operations it is not suitable for measuring MFLOPs. Pure FP loads do not use an FP execution pipe and are counted with UnitMask 7.

| UnitMask | Description                                                                    |
|----------|--------------------------------------------------------------------------------|
| 1        | Pipe1 dispatches. (Float mul/div/sqrt, store/convert, vec-int add/sub/logical) |
| 0        | Pipe0 dispatches. (Float add/sub, vec-int mul, vec-int add/sub/logical)        |

##### PMCx001 FP Scheduler Empty

The number of cycles in which the FPU is empty. Invert this ([MSRC001\\_00\[03:00\]\[Inv\]==1](#)) to count cycles in which at least one FPU operation is present in the FPU.

##### PMCx002 Dispatched Fast Flag FPU Operations

The number of FPU operations that use the fast flag interface (e.g. FCOMI, COMISS, COMISD, UCOMISS, UCOMISD, MOVD, CVTSD2SI). This event is a speculative event.

##### PMCx003 Retired SSE/AVX Operations

The number of SSE/AVX operations retired. The number of events logged per cycle can vary from 0 to 8.

| UnitMask | Description                                |
|----------|--------------------------------------------|
| 7        | Reserved.                                  |
| 6        | Double precision divide/square root FLOPS. |
| 5        | Double precision multiply FLOPS.           |
| 4        | Double precision add/subtract FLOPS.       |
| 3        | Reserved.                                  |
| 2        | Single-precision divide/square root FLOPS. |
| 1        | Single-precision multiply FLOPS.           |

|   |                                      |
|---|--------------------------------------|
| 0 | Single-precision add/subtract FLOPS. |
|---|--------------------------------------|

### PMCx005 Retired Serializing Ops

The number of serializing uops retired. A bottom-executing uop is not issued until it is the oldest non-retired uop in the FPU. A control-renaming uop requires a rename from a limited pool of control renames.

| UnitMask | Description                        |
|----------|------------------------------------|
| 7:4      | Reserved.                          |
| 3        | x87 control-renaming uops retired. |
| 2        | x87 bottom-executing uops retired. |
| 1        | SSE control-renaming uops retired. |
| 0        | SSE bottom-executing uops retired. |

### PMCx011 Retired x87 Floating Point Operations

The number of x87 floating point ops that have retired.

| UnitMask | Description           |
|----------|-----------------------|
| 7:3      | Reserved.             |
| 2        | Divide and fsqrt ops. |
| 1        | Multiply ops.         |
| 0        | Add/subtract ops.     |

### 3.23.2 PMCx0[3F:20] Events (LS)

#### PMCx020 Segment Register Loads

The number of segment register loads performed.

| UnitMask | Description |
|----------|-------------|
| 7        | Reserved.   |
| 6        | HS          |
| 5        | GS          |
| 4        | FS          |
| 3        | DS          |
| 2        | SS          |
| 1        | CS          |
| 0        | ES          |

#### PMCx021 Pipeline Restart Due to Self-Modifying Code

The number of pipeline restarts that were caused by self-modifying code (a store that hits any instruction that's been fetched for execution beyond the instruction doing the store).

**PMCx022 Pipeline Restart Due to Probe Hit**

The number of pipeline restarts caused by invalidating probes that hit load out-of-order with respect to other load.

| UnitMask | Description                                              |
|----------|----------------------------------------------------------|
| 7:2      | Reserved.                                                |
| 1        | Restarts due to evictions caused by fills.               |
| 0        | Restarts due to evictions caused by invalidating probes. |

**PMCx024 Locked Operations**

This event covers locked operations performed and their execution time. The execution time represented by the cycle counts is typically overlapped to a large extent with other instructions. The non-speculative cycles event is suitable for event-based profiling of lock operations that tend to miss in the cache.

| UnitMask | Description                                                      |
|----------|------------------------------------------------------------------|
| 7:3      | Reserved.                                                        |
| 2        | The number of cycles to unlock \$line (not including cache miss) |
| 1        | The number cycles to acquire bus lock                            |
| 0        | The number of locked instructions executed                       |

**PMCx026 Retired CLFLUSH Instructions**

The number of CLFLUSH instructions retired.

**PMCx027 Retired CPUID Instructions**

The number of CPUID instructions retired.

**PMCx029 LS Dispatch**

Counts the number of transactions dispatched to load-store unit.

| UnitMask | Description     |
|----------|-----------------|
| 7:3      | Reserved.       |
| 2        | Load-op-Stores. |
| 1        | Stores.         |
| 0        | Loads.          |

**PMCx02A Canceled Store to Load Forward Operations**

Counts the number of missed store to load forward opportunities which resulted in blocks.

| UnitMask | Description                          |
|----------|--------------------------------------|
| 2        | Block due to store being misaligned. |

|   |                                                             |
|---|-------------------------------------------------------------|
| 1 | Block due to store being smaller than the load.             |
| 0 | Block due to address mismatch (starting byte not the same). |

### 3.23.3 PMCx0[5F:40] Events (DC)

#### PMCx040 Data Cache Accesses

The number of accesses to the data cache for load and store references. This may include certain microcode scratchpad accesses, although these are generally rare. Each increment represents an eight-byte access, although the instruction may only be accessing a portion of that. This event is a speculative event. This event counts all loads and stores that access the cache, that are not prefetch requests, regardless of hit or miss. You can determine data cache hit by looking at event [PMCx041](#) that is the number of data cache misses. MAB hit is not contained.

#### PMCx041 Data Cache Misses

The number of data cache references which miss in the data cache and allocate a MAB. This event is a speculative event. This event counts the number of MAB allocations caused by DC misses. This event does not count MAB allocations for state change requests or prefetch requests.

#### PMCx042 Data Cache Refills from L2 or Northbridge

The number of data cache refills satisfied from the L2 cache (and/or the northbridge), per the UnitMask. This event includes refills for prefetch requests and data returned from state change operations. The UnitMask selects lines in one or more specific coherency states. Each increment reflects a 64-byte transfer. If UnitMask[0] is selected it might be less than 64-bytes. This event is a speculative event.

| UnitMask | Description                   |
|----------|-------------------------------|
| 7:5      | Reserved.                     |
| 4        | Modified                      |
| 3        | Owned                         |
| 2        | Exclusive                     |
| 1        | Shared                        |
| 0        | Non-cacheable return of data. |

#### PMCx043 Data Cache Refills from the northbridge

The number of L1 cache refills satisfied from the northbridge (DRAM or another processor's cache), as opposed to the L2. The UnitMask selects lines in one or more specific coherency states. Each increment reflects a 64-byte transfer. This event is a speculative event.

| UnitMask | Description |
|----------|-------------|
| 7:5      | Reserved.   |
| 4        | Modified    |
| 3        | Owned       |
| 2        | Exclusive   |
| 1        | Shared      |

|   |                          |
|---|--------------------------|
| 0 | Non-cacheable read data. |
|---|--------------------------|

### PMCx044 Data Cache Lines Evicted

The UnitMask may be used to count only victims in specific coherency states. Each increment represents a 64-byte transfer. Lines brought into the data cache by PrefetchNTA instructions are evicted directly to system memory (if dirty) or invalidated (if clean). This event is a speculative event.

| UnitMask | Description        |
|----------|--------------------|
| 7:5      | Reserved.          |
| 4        | Modified eviction  |
| 3        | Owned eviction     |
| 2        | Exclusive eviction |
| 1        | Shared eviction    |
| 0        | Evicted from probe |

### PMCx045 L1 DTLB Miss and L2 DTLB Hit

The number of data cache accesses that miss in the L1 DTLB and hit in the L2 DTLB. This event is a speculative event.

### PMCx046 DTLB Miss

The number of data cache accesses that miss in both the L1 and L2 DTLBs. This event is a speculative event.

| UnitMask | Description                   |
|----------|-------------------------------|
| 7:4      | Reserved.                     |
| 3        | Count loads that miss L2TLB.  |
| 2        | Count stores that miss L2TLB. |
| 1        | Count loads that miss L1TLB.  |
| 0        | Count stores that miss L1TLB. |

### PMCx047 Misaligned Accesses

The number of data cache accesses that are misaligned. These are accesses which cross the boundary as specified by UnitMask. Misaligned accesses incur at least an extra cache access and an extra cycle of latency on reads. This event is a speculative event.

| UnitMask | Description                                       |
|----------|---------------------------------------------------|
| 7:2      | Reserved.                                         |
| 1        | Number of misaligns that cross a 4kb boundary     |
| 0        | Number of misaligns that cross a 16-byte boundary |

### PMCx04B Prefetch Instructions Dispatched

The number of prefetch instructions dispatched by the decoder. Such instructions may or may not cause a cache

line transfer. All Dcache and L2 accesses, hits and misses by prefetch instructions, except for prefetch instructions that collide with an outstanding hardware prefetch, are included in these events. This event is a speculative event.

| UnitMask | Description                       |
|----------|-----------------------------------|
| 7:3      | Reserved.                         |
| 2        | NTA (PrefetchNTA)                 |
| 1        | Store (PrefetchW)                 |
| 0        | Load (Prefetch, PrefetchT0/T1/T2) |

### PMCx04C DCACHE Misses by Locked Instructions

The number of cacheable locked operations that miss in the data cache. Cacheable locks are defined as locks that hit write back memory space and are not misaligned.

### PMCx04D L1 DTLB Hit

The number of data cache accesses that hit in the L1 DTLB. This event is a speculative event.

| UnitMask | Description   |
|----------|---------------|
| 7:2      | Reserved.     |
| 1        | L1 2M TLB hit |
| 0        | L1 4K TLB hit |

### PMCx052 Ineffective Software Prefetchs

The number of software prefetches that do not cause an actual data cache refill. The unit mask may be used to determine the specific cause.

| UnitMask | Description                                                                       |
|----------|-----------------------------------------------------------------------------------|
| 7:4      | Reserved.                                                                         |
| 3        | SW Prefetch hit in L2.                                                            |
| 2        | SW prefetches that don't get a MAB and don't cause <a href="#">PMCx052</a> [1,0]. |
| 1        | Software prefetch hit a pending fill.                                             |
| 0        | Software prefetch hit in the data cache.                                          |

### PMCx054 Global Page Invalidations

This event counts TLB flushes that flush TLB entries that have the global bit set.

### 3.23.4 PMCx[8,1:0][7F:60] Events (BU)

### PMCx062 Command Related to Read Block Operations

| UnitMask | Description |
|----------|-------------|
| 7        | Reserved.   |

|   |                                |
|---|--------------------------------|
| 6 | Read Block Speculative Shared. |
| 5 | RdBlkSpecMod.                  |
| 4 | RdBlkSpec.                     |
| 3 | Reserved.                      |
| 2 | Read Block Shared.             |
| 1 | RdBlkMod.                      |
| 0 | Read Block.                    |

### PMCx063 Command Related to Change to Dirty Operations

| UnitMask | Description      |
|----------|------------------|
| 7:5      | Reserved.        |
| 4        | Change to Dirty. |
| 3:0      | Reserved.        |

### PMCx065 Memory Requests by Type

These events reflect accesses to memory of each region type (as defined by MTRR or PAT settings). UnitMask[1] and UnitMask[7] reflect full 64 byte writes or full or partial 32 byte writes.

| UnitMask | Description                             |
|----------|-----------------------------------------|
| 7        | Streaming store (SS) requests.          |
| 1        | Request to write-combining (WC) memory. |
| 0        | Requests to non-cacheable (UC) memory.  |

### PMCx067 Data Cache Prefetches

| UnitMask | Description           |
|----------|-----------------------|
| 7:4      | Reserved.             |
| 3        | Prefetch hits on MAB. |
| 2        | Reserved.             |
| 1        | Prefetch attempts.    |
| 0        | Reserved.             |

## PMCx068 MAB Requests

These events reflect utilization of the Miss Address Buffers (MABs), which handle L1 cache misses. The UnitMask is an encoded value which selects one of the IC or DC miss buffers. EventSelect 68h counts the number of misses handled by the selected MAB; EventSelect 69h counts the number of cycles the selected MAB is busy waiting for the refill response.

When used together, these two events provide a measure of the average refill latency seen by the selected MAB, which is the number of cycles spent waiting (EventSelect 69h) divided by the number of requests (EventSelect 68h). This calculation gives the most direct indication of average system latency for Dcache and Icache refills, respectively. For other entries this value typically includes queuing delays caused by resource contention with prior refills.

| UnitMask | Description                                                                                                                                                                                                                                                                                                                                                              |      |            |         |                        |         |                        |     |                    |     |                    |         |          |

| 0Ch      | Any IC miss buffer                                                                                                                                                                                                                                                                                                                                                       |      |            |         |                        |         |                        |     |                    |     |                    |         |          |
| FFh-0Dh  | Reserved                                                                                                                                                                                                                                                                                                                                                                 |      |            |         |                        |         |                        |     |                    |     |                    |         |          |

## PMCx069 MAB Wait Cycles

See [PMCx068](#).

| UnitMask | Description                                                 |
|----------|-------------------------------------------------------------|
| 7:0      | <b>BufferID.</b><br>See: <a href="#">PMCx068</a> [BufferN]. |

## PMCx06C System Response by Coherence State

The number of responses from the L2I for cache refill requests. The UnitMask may be used to select specific cache coherency states. Each of {Exclusive, Modified, Shared} represents one 64-byte cache line transferred from the L2I (DRAM, L2 cache, or the L1 cache of another core) to the data cache or instruction cache.

- Modified responses may be for Dcache store miss refills, PrefetchW software prefetches, or Change-to-Dirty requests that get a dirty probe hit in another cache.
- Exclusive responses may be for:
  - Dcache load miss refill.
  - Software prefetches.
- Shared responses may be for:
  - Icache refill.
  - Any request that hits a clean line in another cache.
- Change-to-Dirty success response is for a Dcache upgrade request (store hit to a shared line).
- Uncacheable response is for all uncacheable system requests.

| UnitMask | Description |
|----------|-------------|
| 7        | Reserved.   |

|   |                          |
|---|--------------------------|
| 6 | Uncacheable.             |
| 5 | Change-to-Dirty success. |
| 4 | Data Error.              |
| 3 | Owned.                   |
| 2 | Shared.                  |
| 1 | Modified.                |
| 0 | Exclusive.               |

### PMCx06D Data Written to System

The number of 16-byte data transfers from the processor to the system. Note that a dirty cache line writeback would cause four increments. An IO write would cause two increments: one for the mask and one for the data.

| UnitMask | Description                                       |
|----------|---------------------------------------------------|
| 7:6      | Reserved.                                         |
| 5        | Data for Write Combine context flush.             |
| 4        | Byte Enable Mask for Write Combine context flush. |
| 3        | Data for uncacheable or IO store.                 |
| 2        | Byte Enable Mask for uncacheable or IO store.     |
| 1        | Instruction attribute evictions.                  |
| 0        | Data line evictions.                              |

### PMCx075 Cache Cross-invalidates

These reflect internal probes for Icache or Dcache misses that hit in the Dcache or Icache, causing the line to be invalidated. These may result from code modification, data being located too close to code, or virtual address aliasing. The aliasing cases arise when a physical memory location is referenced via two or more virtual addresses which differ in bits 14:12. Such aliasing cases are generally uncommon.

| UnitMask | Description                                                                                             |
|----------|---------------------------------------------------------------------------------------------------------|
| 7        | Reserved.                                                                                               |
| 6        | DC probe rejected late.                                                                                 |
| 5        | DC probe rejected early.                                                                                |
| 4        | IC hits DC Clean Line (reading code).                                                                   |
| 3        | IC Invalidates DC Dirty Line (execution of recently modified code, or modified data too close to code). |
| 2        | IC Invalidates IC (aliasing).                                                                           |
| 1        | DC Invalidates DC (CD or WBINVD).                                                                       |
| 0        | DC Invalidates IC (modification of cached instructions, or of data located too close to code).          |

### PMCx076 CPU Clocks not Halted

The number of clocks that the CPU is not in a halted state (due to STPCLK or a HLT instruction). Note: this

event allows system idle time to be automatically factored out from IPC (or CPI) measurements, providing the OS halts the CPU when going idle. If the OS goes into an idle loop rather than halting, such calculations are influenced by the IPC of the idle loop.

PMCx07D: Reserved. See [L2IPMCx07D \[Requests to L2 Cache\]](#).

PMCx07E: Reserved. See [L2IPMCx07E \[L2 Cache Misses\]](#).

PMCx07F: Reserved. See [L2IPMCx07F \[L2 Fill/Writeback\]](#).

### PMCx162 PDC Miss

Counts the number of PDC miss events specified by the UnitMask. BOZO BtEnh#18928=Open.

| UnitMask | Description         |
|----------|---------------------|
| 7        | Reserved.           |

| 3        | Reserved.           |
| 2        | Host: PML4E Level.  |
| 1        | Host: PDPE Level.   |
| 0        | Host: PDE Level.    |

### 3.23.5 PMCx[1:0][9F:80] Events (IC)

Note: All instruction cache events are speculative events unless specified otherwise.

#### PMCx080 Instruction Cache Fetches

The number of successful instruction cache accesses by the instruction fetcher that result in data being sent to the decoder. Each access is an aligned 32 byte read, from which a varying number of instructions may be decoded.

#### PMCx081 Instruction Cache Misses

The number of instruction fetches and prefetch requests that miss in the instruction cache. This is typically equal to or very close to the sum of events 82h and 83h. Each miss results in a 64-byte cache line refill.

#### PMCx082 Instruction Cache Refills from L2

The number of instruction cache refills satisfied from the L2 cache. Each increment represents one 64-byte cache line transfer.

#### PMCx083 Instruction Cache Refills from System

The number of instruction cache refills from system memory (or another cache). Each increment represents one 64-byte cache line transfer.

**PMCx084 L1 ITLB Miss, L2 ITLB Hit**

The number of instruction fetches that miss in the L1 ITLB but hit in the L2 ITLB.

**PMCx085 ITLB Miss**

The number of instruction fetches that miss in the 4K ITLB and 2M ITLB.

| UnitMask | Description                       |
|----------|-----------------------------------|
| 7:2      | Reserved.                         |
| 1        | Instruction fetches to a 2M page. |
| 0        | Instruction fetches to a 4K page. |

**PMCx087 Instruction Fetch Stall**

The number of cycles the instruction fetcher is stalled. This may be for a variety of reasons such as branch predictor updates, unconditional branch bubbles, far jumps and cache misses, among others. May be overlapped by instruction dispatch stalls or instruction execution, such that these stalls don't necessarily impact performance.

**PMCx088 Return Stack Hits**

The number of near return instructions (RET or RET Iw) that get their return address from the return address stack (i.e. where the stack has not gone empty). This may include cases where the address is incorrect (return mispredicts). This may also include speculatively executed false-path returns. Return mispredicts are typically caused by the return address stack underflowing, however they may also be caused by an imbalance in calls vs. returns, such as doing a call but then popping the return address off the stack.

This event cannot be reliably compared with events C9h and CAh (such as to calculate percentage of return mispredicts due to an empty return address stack), since it may include speculatively executed false-path returns that are not included in those retire-time events.

**PMCx089 Return Stack Overflows**

The number of (near) call instructions that cause the return address stack to overflow. When this happens, the oldest entry is discarded. This count may include speculatively executed calls.

**PMCx08B Instruction Cache Victims**

The number of cachelines evicted from the instruction cache to the L2.

**PMCx08C Instruction Cache Lines Invalidated**

The number of instruction cache lines invalidated.

| UnitMask | Description                      |
|----------|----------------------------------|
| 7:2      | Reserved.                        |
| 1        | IC invalidate due to a BU probe. |

|   |                                   |
|---|-----------------------------------|
| 0 | IC invalidate due to an LS probe. |
|---|-----------------------------------|

### PMCx099 ITLB Reloads

The number of ITLB reload requests.

### PMCx09A ITLB Reloads Aborted

The number of ITLB reloads aborted.

### PMCx19A Retired Indirect Branch Info

| UnitMask | Description                                                                                                                                                                |
|----------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 7:2      | Reserved.                                                                                                                                                                  |
| 1        | Retired Mispredicted Indirect Branch Instruction. Retired Mispredicted Near Unconditional jump with target specified in Register or Memory. This event is non-speculative. |
| 0        | Retired Indirect branch Instruction. Retired Near Unconditional jump with target specified in Register or Memory. This event is non-speculative.                           |

## 3.23.6 PMCx[1,0][DF:C0] Events (EX, DE)

### PMCx0C0 Retired Instructions

The number of instructions retired (execution completed and architectural state updated). This count includes exceptions and interrupts - each exception or interrupt is counted as one instruction.

### PMCx0C1 Retired uops

The number of micro-ops retired. This includes all processor activity (instructions, exceptions, interrupts, microcode assists, etc.).

### PMCx0C2 Retired Branch Instructions

The number of branch instructions retired. This includes all types of architectural control flow changes, including exceptions and interrupts.

### PMCx0C3 Retired Mispredicted Branch Instructions

The number of branch instructions retired, of any type, that were not correctly predicted in either target or direction. This includes those for which prediction is not attempted (far control transfers, exceptions and interrupts), and excludes resyncs.

### PMCx0C4 Retired Taken Branch Instructions

The number of taken branches that were retired. This includes all types of architectural control flow changes, including exceptions and interrupts, and excludes resyncs.

**PMCx0C5 Retired Taken Branch Instructions Mispredicted**

The number of retired taken branch instructions that were mispredicted, and excludes resyncs.

**PMCx0C6 Retired Far Control Transfers**

The number of far control transfers retired including far call/jump/return, IRET, SYSCALL and SYSRET, plus exceptions and interrupts, and excludes resyncs. Far control transfers are not subject to branch prediction.

**PMCx0C7 Retired Branch Resyncs**

The number of resync branches. These reflect pipeline restarts due to certain microcode assists and events such as writes to the active instruction stream, among other things. Each occurrence reflects a restart penalty similar to a branch mispredict. This is relatively rare.

**PMCx0C8 Retired Near Returns**

The number of near return instructions (RET or RET Iw) retired.

**PMCx0C9 Retired Near Returns Mispredicted**

A near return instruction was retired that mispredicted in either target or direction.

**PMCx0CA Retired Mispredicted Taken Branch Instructions due to Target Mismatch**

A taken branch instruction was retired that mispredicted in target address (but not in direction).

**PMCx0CB Retired MMX/FP Instructions**

A floating point (x87, MMX, or SSE) instruction was retired. The UnitMask allows the distinction between x87/MMX and SSE instructions. Since this event includes non-numeric instructions it is not suitable for measuring MFLOPS.

| UnitMask | Description                                                       |
|----------|-------------------------------------------------------------------|
| 7:2      | Reserved.                                                         |
| 1        | SSE floating point instruction was retired (SSE, SSE2, SSE3, MNI) |
| 0        | x87 or MMX™ instruction was retired                               |

**PMCx0CD Interrupts-Masked Cycles**

The number of processor cycles where interrupts are masked (EFLAGS.IF = 0). Using edge-counting with this event gives the number of times IF is cleared; dividing the cycle-count value by this value gives the average length of time that interrupts are disabled on each instance. Compare the edge count with [PMCx0CF](#) to determine how often interrupts are disabled for interrupt handling vs. other reasons (e.g. critical sections).

**PMCx0CE Interrupts-Masked Cycles with Interrupt Pending**

The number of processor cycles where interrupts are masked (EFLAGS.IF = 0) and an interrupt is pending.

Using edge-counting with this event and comparing the resulting count with the edge count for [PMCx0CD](#) gives the proportion of interrupts for which handling is delayed due to prior interrupts being serviced, critical sections, etc. The cycle count value gives the total amount of time for such delays. The cycle count divided by the edge count gives the average length of each such delay.

### PMCx0CF Interrupts Taken

The number of hardware interrupts taken. This does not include software interrupts (INT n instruction).

### PMCx0DB FPU Exceptions

The number of floating point unit exceptions for microcode assists. The UnitMask may be used to isolate specific types of exceptions.

| UnitMask | Description             |
|----------|-------------------------|
| 7:4      | Reserved.               |
| 3        | SSE and x87 microtraps  |
| 2        | SSE reclass microfaults |
| 1        | SSE retype microfaults  |
| 0        | x87 reclass microfaults |

### PMCx0D[F:C] DR[3:0] Breakpoint Matches

Table 229: [Register Mapping](#) for [PMCx0D\[F:C\]](#)

| Register | Function |
|----------|----------|
| PMCx0DC  | DR0      |
| PMCx0DD  | DR1      |
| PMCx0DE  | DR2      |
| PMCx0DF  | DR3      |

The number of matches on the address in breakpoint register DR0, per the breakpoint type specified in DR7. The breakpoint does not have to be enabled. Each instruction breakpoint match incurs an overhead of about 120 cycles; load/store breakpoint matches do not incur any overhead.

### PMCx1CF Tagged IBS Ops

Number of ops tagged by IBS.

### PMCx1D0 Tagged IBS Ops Retired

The number of retired tagged IBS operations.

### 3.24 L2I Performance Counter Events

#### L2IPMCx060 Command Related to Victim Buffers

| UnitMask | Description                                        |
|----------|----------------------------------------------------|
| 7        | <b>Lock.</b>                                       |

#### L2IPMCx061 Command Related to Masked Operations

Count Masked Byte and DW reads and writes to the NB. Byte sized read and write commands can request the transfer of up to 32 bytes. DW sized read and write commands can request the transfer of up to 32 DW's. Combining of the WC memory type can cause 1 B/DW write to represent multiple stores.

### L2IPMCx06C Response From System on Cache Refills

The number of responses from the system for cache refill requests. The UnitMask may be used to select specific cache coherency states. Each increment represents one 64 B cache line transferred from the system (DRAM or another cache, including another core on the same node) to the data cache, instruction cache or L2 cache (for data prefetcher and TLB table walks). Modified-state responses may be for Dcache store miss refills, PrefetchW software prefetches, hardware prefetches for a store-miss stream, or Change-to-Dirty requests that get a dirty (Owned) probe hit in another cache. Exclusive responses may be for any Icache refill, Dcache load miss refill, other software prefetches, hardware prefetches for a load-miss stream, or TLB table walks that miss in the L2 cache; Shared responses may be for any of those that hit a clean line in another cache.

### L2IPMCx07D Requests to L2 Cache

| UnitMask | Description                                  |
|----------|----------------------------------------------|
| 7        | Reserved.                                    |
| 6        | <b>PrefReq.</b> L2 cache prefetcher request. |
| 5:4      | Reserved.                                    |
| 3        | <b>NbPrbReq.</b> NB probe request.           |
| 2        | Reserved.                                    |
| 1        | <b>DcFill.</b> DC fill.                      |
| 0        | <b>IcFill.</b> IC fill.                      |

### L2IPMCx07E L2 Cache Misses

The number of requests that miss in the L2 cache. This may include some amount of speculative activity. The IC-fill-miss and DC-fill-miss events tend to mirror the Icache and Dcache refill-from-system [PMCx083](#) and [PMCx043](#), and tend to include more speculative activity than those events.

| 4 | Reserved. Deprecated STC trip point is crossed. |
| 3 | Reserved. Deprecated STC trip point active.     |
| 2 | Number of times the HTC trip point is crossed   |

### NBPMCx0E9 CPU/IO Requests to Memory/IO

These events reflect request flow between units and nodes, as selected by the UnitMask. The UnitMask is divided into two fields: request type (CPU or IO access to IO or Memory) and source/target location (local vs. remote). One or more requests types must be enabled via bits 3:0, and at least one source and one target location must be selected via bits 7:4. Each event reflects a request of the selected type(s) going from the selected source(s) to the selected target(s).

Not all possible paths are supported. The following table shows the UnitMask values that are valid for each request type:

| Source/Target    | CPU to Mem | CPU to IO | IO to Mem | IO to IO |
|------------------|------------|-----------|-----------|----------|
| Local -> Local   | A8h        | A4h       | A2h       | A1h      |
| Local -> Remote  | 98h        | 94h       | 92h       | 91h      |
| Remote -> Local  | -          | 64h       | -         | 61h      |
| Remote -> Remote | -          | -         | -         | -        |

Any of the mask values shown may be logically ORed to combine the events. For instance, local CPU requests to both local and remote nodes would be  $A8h \mid 98h = B8h$ . Any CPU to any IO would be  $A4h \mid 94h \mid 64h = F4h$  (but remote CPU to remote IO requests would not be included).

Note: It is not possible to tell from these events how much data is going in which direction, as there is no distinction between reads and writes. Also, particularly for IO, the requests may be for varying amounts of data, anywhere from one to sixty-four bytes. [NBPMCx0E5](#) provides an indication of 32- and 64-byte read and write transfers for such requests (although from the target point of view). For a direct measure of the amount and direction of data flowing between nodes, use events F6h, F7h and F8h.

| UnitMask | Description      |
|----------|------------------|
| 7        | From local node  |
| 6        | From remote node |
| 5        | To local node    |
| 4        | To remote node   |
| 3        | CPU to Mem       |
| 2        | CPU to IO        |
| 1        | IO to Mem        |
| 0        | IO to IO         |

### NBPMCx0EA Cache Block Commands

The number of requests made to the system for cache line transfers or coherency state changes, by request type. Each increment represents one cache line transfer, except for Change-to-Dirty. If a Change-to-Dirty request hits on a line in another processor's cache that's in the Owned state, it causes a cache line transfer, otherwise

there is no data transfer associated with Change-to-Dirty requests.

| UnitMask | Description                                                   |
|----------|---------------------------------------------------------------|
| 7:6      | Reserved.                                                     |
| 5        | Change-to-Dirty (first store to clean block already in cache) |
| 4        | Read Block Modified (Dcache store miss refill)                |
| 3        | Read Block Shared (Icache refill)                             |
| 2        | Read Block (Dcache load miss refill)                          |
| 1        | Reserved.                                                     |
| 0        | Victim Block (Writeback)                                      |

### NBPMCx0EB Sized Commands

The number of Sized Read/Write commands handled by the System Request Interface (local processor and hostbridge interface to the system). These commands may originate from the processor or hostbridge. Typical uses of the various Sized Read/Write commands are given in the UnitMask table. See [NBPMCx0E5](#), which covers commonly-used block sizes for these requests, and [NBPMCx0EC](#), which provides a separate measure of Hostbridge accesses.

| UnitMask | Description                                                                                                                                    |
|----------|------------------------------------------------------------------------------------------------------------------------------------------------|
| 7:6      | Reserved.                                                                                                                                      |
| 5        | SzRd DW (1-16 DWORDs). Typical Usage: Block-oriented DMA reads, typically cache-line size.                                                     |
| 4        | SzRd Byte (4 bytes). Typical Usage: Legacy or mapped IO.                                                                                       |
| 3        | Posted SzWr DW (1-16 DWORDs). Typical Usage: Block-oriented DMA writes, often cache-line sized; also processor Write Combining buffer flushes. |
| 2        | Posted SzWr Byte (1-32 bytes). Typical Usage: Sub-cache-line DMA writes, size varies; also flushes of partially-filled Write Combining buffer. |
| 1        | Non-Posted SzWr DW (1-16 DWORDs). Typical Usage: Legacy or mapped IO, typically 1 DWORD.                                                       |
| 0        | Non-Posted SzWr Byte (1-32 bytes). Typical Usage: Legacy or mapped IO, typically 1-4 bytes.                                                    |

### NBPMCx0EC Probe Responses and Upstream Requests

This covers two unrelated sets of events: cache probe results, and requests received by the hostbridge from devices on non-coherent links.

**Probe results:** These events reflect the results of probes sent from a memory controller to local caches. They provide an indication of the degree data and code is shared between processors (or moved between processors due to process migration). The dirty-hit events indicate the transfer of a 64-byte cache line to the requestor (for a read or cache refill) or the target memory (for a write). The system bandwidth used by these, in terms of bytes per unit of time, may be calculated as 64 times the event count, divided by the elapsed time. Sized writes to memory that cover a full cache line do not incur this cache line transfer -- they simply invalidate the line and are reported as clean hits. Cache line transfers occur for Change2Dirty requests that hit cache lines in the Owned state. (Such cache lines are counted as Modified-state refills for [PMCx06C](#), System Read Responses.)

**Upstream requests:** The upstream read and write events reflect requests originating from a device on a local IO link. The two read events allow display refresh traffic in a UMA system to be measured separately from

other DMA activity. Display refresh traffic is typically dominated by 64-byte transfers. Non-display-related DMA accesses may be anywhere from 1 to 64 bytes in size, but may be dominated by a particular size such as 32 or 64 bytes, depending on the nature of the devices. [NBPMCx0E5](#) can provide a measure of 32- and 64-byte accesses by the hostbridge (possibly combined with write combining buffer flush activity from the processor, although that can be factored out via [NBPMCx0E5](#)).

| UnitMask | Description                                                                     |
|----------|---------------------------------------------------------------------------------|
| 7        | Upstream non-ISOC writes                                                        |
| 6        | Upstream ISOC writes                                                            |
| 5        | Upstream non-display refresh reads                                              |
| 4        | Upstream display refresh/ISOC reads                                             |
| 3        | Probe hit dirty with memory cancel (probed by DMA read or cache refill request) |
| 2        | Probe hit dirty without memory cancel (probed by Sized Write or Change2Dirty)   |
| 1        | Probe hit clean                                                                 |
| 0        | Probe miss                                                                      |

### 3.25.3 PMCx0F[F:0] Events (ONION, Crossbar)

### 3.25.4 NBPMCx1E[F:0] Events (Crossbar)

#### **NBPMCx1E0 CPU to DRAM Requests to Target Node**

This event counts all DRAM reads and writes generated by cores on the local node to the targeted node in the coherent fabric. This counter can be used to observe processor data affinity in NUMA aware operating systems.

| UnitMask | Description               |
|----------|---------------------------|
| 7        | From Local node to Node 7 |
| 6        | From Local node to Node 6 |
| 5        | From Local node to Node 5 |
| 4        | From Local node to Node 4 |
| 3        | From Local node to Node 3 |
| 2        | From Local node to Node 2 |
| 1        | From Local node to Node 1 |
| 0        | From Local node to Node 0 |

#### **NBPMCx1E1 IO to DRAM Requests to Target Node**

This event counts all DRAM reads and writes generated by IO devices attached to the IO links of the local node the targeted node in the coherent fabric. This counter can be used to observe IO device data affinity in NUMA aware operating systems.

| UnitMask | Description               |
|----------|---------------------------|
| 7        | From Local node to Node 7 |
| 6        | From Local node to Node 6 |

|   |                           |
|---|---------------------------|
| 5 | From Local node to Node 5 |
| 4 | From Local node to Node 4 |
| 3 | From Local node to Node 3 |
| 2 | From Local node to Node 2 |
| 1 | From Local node to Node 1 |
| 0 | From Local node to Node 0 |

### **NBPMCx1E2 CPU Read Command Latency to Target Node 0-3**

This event counts the number of NB clocks from when the targeted command is received in the NB to when the targeted command completes. This event only tracks one outstanding command at a time. To determine latency between the local node and a remote node set UnitMask[7:4] to select the node and UnitMask[3:0] to select the read command type. The count returned by the counter should be divided by the count returned by [NBPMCx1E3](#) to determine the average latency for the command type.

| UnitMask | Description               |
|----------|---------------------------|
| 7        | From Local node to Node 3 |
| 6        | From Local node to Node 2 |
| 5        | From Local node to Node 1 |
| 4        | From Local node to Node 0 |
| 3        | Change-to-Dirty           |
| 2        | Read block modified       |
| 1        | Read block shared         |
| 0        | Read block                |

### **NBPMCx1E3 CPU Read Command Requests to Target Node 0-3**

This event counts the number of requests that a latency measurement is made for using [NBPMCx1E2](#). To determine the number of commands that a latency measurement are made for between the local node and a remote node set UnitMask[7:4] to select the node and UnitMask[3:0] to select the read command type.

| UnitMask | Description               |
|----------|---------------------------|
| 7        | From Local node to Node 3 |
| 6        | From Local node to Node 2 |
| 5        | From Local node to Node 1 |
| 4        | From Local node to Node 0 |
| 3        | Change-to-Dirty           |
| 2        | Read block modified       |
| 1        | Read block shared         |
| 0        | Read block                |

### **NBPMCx1E4 CPU Read Command Latency to Target Node 4-7**

This event counts the number of NB clocks from when the targeted command is received in the NB to when the

targeted command completes. This event only tracks one outstanding command at a time. To determine latency between the local node and a remote node set UnitMask[7:4] to select the node and UnitMask[3:0] to select the read command type. The count returned by the counter should be divided by the count returned by [NBPMCx1E5](#) to determine the average latency for the command type.

| UnitMask | Description               |
|----------|---------------------------|
| 7        | From Local node to Node 7 |
| 6        | From Local node to Node 6 |
| 5        | From Local node to Node 5 |
| 4        | From Local node to Node 4 |
| 3        | Change-to-Dirty           |
| 2        | Read block modified       |
| 1        | Read block shared         |
| 0        | Read block                |

#### **NBPMCx1E5 CPU Read Command Requests to Target Node 4-7**

This event counts the number of requests that a latency measurement is made for using [NBPMCx1E4](#). To determine the number of commands that a latency measurement are made for between the local node and a remote node set UnitMask[7:4] to select the node and UnitMask[3:0] to select the read command type.

| UnitMask | Description               |
|----------|---------------------------|
| 7        | From Local node to Node 7 |
| 6        | From Local node to Node 6 |
| 5        | From Local node to Node 5 |
| 4        | From Local node to Node 4 |
| 3        | Change-to-Dirty           |
| 2        | Read block modified       |
| 1        | Read block shared         |
| 0        | Read block                |

#### **NBPMCx1E6 CPU Command Latency to Target Node 0-3/4-7**

This event counts the number of NB clocks from when the targeted command is received in the NB to when the targeted command completes. This event only tracks one outstanding command at a time. To determine latency between the local node and a remote node set UnitMask[7:4] to select the node, UnitMask[3] to select the node group and UnitMask[3:0] to select the command type. The count returned by the counter should be divided by the count returned by [NBPMCx1E7](#) to determine the average latency for the command type.

| UnitMask | Description                 |
|----------|-----------------------------|
| 7        | From Local node to Node 3/7 |
| 6        | From Local node to Node 2/6 |
| 5        | From Local node to Node 1/5 |
| 4        | From Local node to Node 0/4 |

|   |                                               |
|---|-----------------------------------------------|
| 3 | Node Group Select. 0=Nodes 0-3. 1= Nodes 4-7. |
| 2 | Victim Block                                  |
| 1 | Write Sized                                   |
| 0 | Read Sized                                    |

### NBPMCx1E7 CPU Requests to Target Node 0-3/4-7

This event counts the number of requests that a latency measurement is made for using [NBPMCx1E6](#). To determine the number of commands that a latency measurement are made for between the local node and a remote node set UnitMask[7:4] to select the node, UnitMask[3] to select the node group and UnitMask[3:0] to select the command type.

| UnitMask | Description                                   |
|----------|-----------------------------------------------|
| 7        | From Local node to Node 3/7                   |
| 6        | From Local node to Node 2/6                   |
| 5        | From Local node to Node 1/5                   |
| 4        | From Local node to Node 0/4                   |
| 3        | Node Group Select. 0=Nodes 0-3. 1= Nodes 4-7. |
| 2        | Victim Block                                  |
| 1        | Write Sized                                   |
| 0        | Read Sized                                    |

### NBPMCx1EB Request Cache Status 1

The probe response type for RdBlkM or ChgToDirty request type.

| UnitMask | Description                     |
|----------|---------------------------------|
| 7        | Track Cache Stat for RdBlkM     |
| 6        | Track Cache Stat for ChgToDirty |
| 5        | Directed Probe                  |
| 4        | Probe Miss                      |
| 3        | Probe Hit M                     |
| 2        | Probe Hit MuW or O              |
| 1        | Probe Hit E                     |
| 0        | Probe Hit S                     |

## 3.25.5 NBPMCx1F[F:0] Events (Memory Controller, Crossbar)

### NBPMCx1F0 Memory Controller Requests

Read/Write requests: The read/write request events reflect the total number of commands sent to the DRAM controller.

Sized Read/Write activity: The Sized Read/Write events reflect 32- or 64-byte transfers (as opposed to other sizes which could be anywhere between 1 and 64 bytes), from either the processor or the Hostbridge (on any node in an MP system). Such accesses from the processor would be due only to write combining buffer flushes,

where 32-byte accesses would reflect flushes of partially-filled buffers. **PMCx065** provides a count of sized write requests associated with WC buffer flushes; comparing that with counts for these events (providing there is very little Hostbridge activity at the same time) gives an indication of how efficiently the write combining buffers are being used. **PMCx065** may also be useful in factoring out WC flushes when comparing these events with the Upstream Requests component of **PMCx06C**.

| UnitMask | Description                                                                |
|----------|----------------------------------------------------------------------------|
| 7        | Read requests sent to the DCT while writes requests are pending in the DCT |
| 6        | 64 Byte Sized Reads                                                        |
| 5        | 32 Bytes Sized Reads                                                       |
| 4        | 64 Bytes Sized Writes                                                      |
| 3        | 32 Bytes Sized Writes                                                      |
| 2        | Prefetch requests sent to the DCT                                          |
| 1        | Read requests (including prefetch requests) sent to the DCT                |
| 0        | Write requests sent to the DCT                                             |

### NBPMCx3EC DRAM Accesses

The number of memory accesses performed by the local DRAM controller. UnitMask[7:0] may be used to isolate the different DRAM page access cases. Page miss cases incur an extra latency to open a page; page conflict cases incur both a page-close as well as page-open penalties. These penalties may be overlapped by DRAM accesses for other requests and don't necessarily represent lost DRAM bandwidth. The associated penalties are as follows:

Page miss: Trcd (DRAM RAS-to-CAS delay)  
 Page conflict: Trp + Trcd (DRAM row-precharge time plus RAS-to-CAS delay)

Each DRAM access represents one 64-byte block of data transferred if the DRAM is configured for 64-byte granularity, or one 32-byte block if the DRAM is configured for 32-byte granularity. (The latter is only applicable to single-channel DRAM systems, which may be configured either way.)

| UnitMask | Description        |
|----------|--------------------|
| 7:6      | Reserved.          |
| 5        | DCT1 Page Conflict |
| 4        | DCT1 Page Miss     |
| 3        | DCT1 Page hit      |
| 2        | DCT0 Page Conflict |
| 1        | DCT0 Page Miss     |
| 0        | DCT0 Page hit      |

### NBPMCx3ED DRAM Controller Page Table Overflows

The number of page table overflows in the local DRAM controller. This table maintains information about which DRAM pages are open. An overflow occurs when a request for a new page arrives when the maximum number of pages are already open. Each occurrence reflects an access latency penalty equivalent to a page con-

flict.

| UnitMask | Description              |
|----------|--------------------------|
| 1        | DCT1 Page Table Overflow |
| 0        | DCT0 Page Table Overflow |

### **NBPMCx3EE Memory Controller DRAM Command Slots Missed**

| UnitMask | Description                            |
|----------|----------------------------------------|
| 1        | DCT1 Command Slots Missed (in MEMCLKs) |
| 0        | DCT0 Command Slots Missed (in MEMCLKs) |

### **NBPMCx3EF Memory Controller Turnarounds**

The number of turnarounds on the local DRAM data bus. UnitMask[7:0] may be used to isolate the different cases. These represent lost DRAM bandwidth, which may be calculated as follows (in bytes per occurrence):

DIMM turnaround:  $\text{DRAM\_width\_in\_bytes} * 2 \text{ edges\_per\_memclk} * 2$   
 R/W turnaround:  $\text{DRAM\_width\_in\_bytes} * 2 \text{ edges\_per\_memclk} * 1$   
 R/W turnaround:  $\text{DRAM\_width\_in\_bytes} * 2 \text{ edges\_per\_memclk} * (\text{Tcl}-1)$

where DRAM\_width\_in\_bytes is 8 or 16 (for single- or dual-channel systems), and Tcl is the CAS latency of the DRAM in memory system clock cycles (where the memory clock for DDR-400, or PC3200 DIMMS, for example, would be 200 MHz).

| UnitMask | Description                        |
|----------|------------------------------------|
| 5        | DCT1 Write to read turnaround      |
| 4        | DCT1 Read to write turnaround      |
| 3        | DCT1 DIMM (chip select) turnaround |
| 2        | DCT0 Write to read turnaround      |
| 1        | DCT0 Read to write turnaround      |
| 0        | DCT0 DIMM (chip select) turnaround |

### 3.26 Fusion Controller Hub Registers

#### 3.26.1 Legacy Block Configuration Registers (IO)

See 3.1 [Register Descriptions and Mnemonics] for a description of the register naming convention.

##### IO000 Dma\_Ch 0

| Bits | Description                                                                    |
|------|--------------------------------------------------------------------------------|
| 15:0 | <b>DmaCh0</b> . Read-write. Reset: 0. DMA1 channel 0 base and current address. |

##### IO002 Dma\_Ch 1

| Bits | Description                                                                    |
|------|--------------------------------------------------------------------------------|
| 15:0 | <b>DmaCh1</b> . Read-write. Reset: 0. DMA1 channel 1 base and current address. |

##### IO004 Dma\_Ch 2

| Bits | Description                                                                    |
|------|--------------------------------------------------------------------------------|
| 15:0 | <b>DmaCh2</b> . Read-write. Reset: 0. DMA1 channel 2 base and current address. |

##### IO006 Dma\_Ch 3

| Bits | Description                                                                    |
|------|--------------------------------------------------------------------------------|
| 15:0 | <b>DmaCh3</b> . Read-write. Reset: 0. DMA1 channel 3 base and current address. |

##### IO008 Dma\_Status

| Bits | Description                                                                                                                                                            |
|------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 7:0  | <b>DmaStatus</b> . Read-write. Reset: 0. Specifies the DMA status register for channels 0-3 for reads; specifies the DMA control register for channels 0-3 for writes. |

##### IO009 Dma\_WriteRequest

| Bits | Description                                                      |
|------|------------------------------------------------------------------|
| 7:0  | <b>DmaWriteRequest</b> . Read-write. Reset: 0. Request register. |

##### IO00A Dma\_WriteMask

| Bits | Description                                                            |
|------|------------------------------------------------------------------------|
| 7:0  | <b>DmaWriteMask</b> . Read-write. Reset: 0. DMA channel mask register. |

**IO00B Dma\_WriteMode**

| Bits | Description                                                    |
|------|----------------------------------------------------------------|
| 7:0  | <b>DmaWriteMode</b> . Read-write. Reset: 0. DMA mode register. |

**IO00C Dma\_Clear**

| Bits | Description                                                                 |
|------|-----------------------------------------------------------------------------|
| 7:0  | <b>DmaClear</b> . Read-write. Reset: 0. Channel 0-3 DMA clear byte pointer. |

**IO00D Dma\_MasterClr**

Dma\_MasterClr register

| Bits | Description                                                                                                        |
|------|--------------------------------------------------------------------------------------------------------------------|
| 7:0  | <b>DmaMasterClr</b> . Read-write. Reset: 0. Write: Channel 0-3 master clear register. Read: Intermediate register. |

**IO00E Dma\_ClrMask**

| Bits | Description                                                           |
|------|-----------------------------------------------------------------------|
| 7:0  | <b>DmaClrmask</b> . Read-write. Reset: 0. Channel 0-3 DMA clear mask. |

**IO00F Dma\_AllMask**

| Bits | Description                                                      |
|------|------------------------------------------------------------------|
| 7:0  | <b>DmaAllMask</b> . Read-write. Reset: 0. General mask register. |

**IO020 IntrCntl1Reg1**

| Bits | Description                                                                                                      |
|------|------------------------------------------------------------------------------------------------------------------|
| 7:0  | <b>IntrCntl1Reg1</b> . Read-write. Reset: 0. IRQ0-7 status and control. Read: IRR, ISR. Write: ICW1, OCW2, OCW3. |

**IO021 IntrCntl1Reg2**

| Bits | Description                                                                                                       |
|------|-------------------------------------------------------------------------------------------------------------------|
| 7:0  | <b>IntrCntl1Reg2</b> . Read-write. Reset: 0. IRQ0-7 status and control. Read: IMR. Write: ICW2, ICW3, ICW4, OCW1. |

**IO022 IMCR\_Index**

| Bits | Description                                                                                                    |
|------|----------------------------------------------------------------------------------------------------------------|
| 7:0  | <b>ImcrIndex</b> . Read-write. Reset: 0. Index port for IMCR register. See <a href="#">IO023 [IMCR_Data]</a> . |

**IO023 IMCR\_Data**

| Bits | Description                                                                                                                               |
|------|-------------------------------------------------------------------------------------------------------------------------------------------|
| 7:0  | <b>ImcrData</b> . Read-write. Reset: 0. Data port for IMCR register. The actual IMCR register is located at index 70h and it is at bit 0. |

**IO040 TimerCh0**

| Bits | Description                                                               |
|------|---------------------------------------------------------------------------|
| 7:0  | <b>TimerCh0</b> . Read-write. Reset: 0. 8254 Timer 1 Counter 0 Data Port. |

**IO041 TimerCh1**

| Bits | Description                                                               |
|------|---------------------------------------------------------------------------|
| 7:0  | <b>TimerCh1</b> . Read-write. Reset: 0. 8254 Timer 1 Counter 1 Data Port. |

**IO042 TimerCh2**

| Bits | Description                                                               |
|------|---------------------------------------------------------------------------|
| 7:0  | <b>TimerCh2</b> . Read-write. Reset: 0. 8254 Timer 1 Counter 2 Data Port. |

**IO043 Tmr1CntrlWord**

| Bits | Description                                                                                                                                                                                                                                                                                                                                                                       |      |            |     |                       |     |                                   |     |                                  |     |                                                  |

### IO060 Keyboard Data

| Bits | Description                                                                                                                                                                                                                      |
|------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 7:0  | <b>Data.</b> Read-write. Reset: 0. Specifies the keyboard controller data port. It should only be read from when <a href="#">IO064[0]</a> reads back 1. It should only be written to when <a href="#">IO064[1]</a> reads back 0. |

### IO061 Nmi Status

| Bits | Description                                                                                                                                                           |
|------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 7    | <b>ParityErrNmi.</b> Read-only. Reset: X. NMI is caused by parity error (either PERR# or SERR#).                                                                      |
| 6    | <b>IoChkNmi.</b> Read-only. Reset: X. NMI is triggered by serial IOCHK.                                                                                               |
| 5    | <b>SpkrClk.</b> Read-only. Reset: X. The output of 8254 timer counter 2.                                                                                              |
| 4    | <b>RefClk.</b> Read-only. Reset: X. The output of 8254 timer counter 1.                                                                                               |
| 3    | <b>IoChkNmiEn.</b> Read-write. Reset: 1. 0=Enable IoChk to NMI generation. 1=Disable IoChk to NMI generation.                                                         |
| 2    | <b>ParityErrNmiEn.</b> Read-write. Reset: 1. 0=Enable Parity Error to NMI generation (from SERR# or PERR#). 1=Disable Parity Error to NMI generation and clear bit 7. |
| 1    | <b>SpkrTmrEnable.</b> Read-write. Reset: 0. 0=Speaker timer off. 1=Speaker timer on.                                                                                  |
| 0    | <b>SpkrEnable.</b> Read-write. Reset: 0. 0=Disable counter 2. 1=Enable counter 2.                                                                                     |

### IO064 Keyboard Status/Control

IF (READ)

| Bits | Description                                                                                                                                                                                                               |
|------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 7    | <b>KeyPar.</b> Read-only. Reset: 0. 1=Keyboard data transmission parity error.                                                                                                                                            |
| 6    | <b>KeyRTO.</b> Read-only. Reset: 0. 1= Receive time out.                                                                                                                                                                  |
| 5    | <b>KeyTTO.</b> Read-only. Reset: 0. 1=Keyboard transmit time out or mouse data available.                                                                                                                                 |
| 4    | <b>KeyEnB.</b> Read-only. Reset: 0. 0=Password protected.                                                                                                                                                                 |
| 3    | <b>CmdData.</b> Read-only. Reset: 0. 1=Between the keyboard command and data ports, the command port at 64h was last written to. 0=Between the keyboard command and data ports, the data port at 60h was last written to. |
| 2    | <b>KeySys.</b> Read-only. Reset: 0. Specifies system flag status. 1=Power up or reset. 1=Soft reset.                                                                                                                      |

|   |                                                                                                 |
|---|-------------------------------------------------------------------------------------------------|
| 1 | <b>KeyIBF</b> . Read-only. Reset: 0. 1=Input buffer full. 0=Ready to receive next command/data. |
| 0 | <b>KeyOBF</b> . Read-only. Reset: 0. 1=Data is available to read back. 0=No data available.     |

ELSE

| Bits | Description                                                           |
|------|-----------------------------------------------------------------------|
| 7:0  | <b>KeyCmd</b> . Write-only. Reset: 0. Specified the keyboard command. |

ENDIF.

#### IO070 RtcAddrPort and NmiMask

| Bits | Description                                                                                                                                                                                                                                                                                                                                         |
|------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 7    | <b>NmiMask</b> . Write-only. Reset: 0. 0=NMI enabled. 1=NMI masked.                                                                                                                                                                                                                                                                                 |
| 6:0  | <b>RtcAddrPort: RTC Address Port</b> . Read-write. Reset: 0. This is used with either internal RTC or external RTC. This port specifies the index to access RTC time registers and the CMOS RAM space. <a href="#">IO073_x0A</a> [DV0] should be programmed first to select bank when accessing the CMOS RAM space. See <a href="#">IO073_x00</a> . |

#### IO071 RtcDataPort

| Bits | Description                                                                                                                                                 |
|------|-------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 7:0  | <b>RtcDataPort: RTC Data Port</b> . Read-write. Reset: 0. This is used with either internal RTC or external RTC in conjunction with <a href="#">IO070</a> . |

#### IO072 Alternate RTC AddrPort

| Bits | Description                                                                                                                                                                                                       |
|------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 7:0  | <b>AlternatRTCAAddrPort</b> . Read-write. Reset: 0. This is used with internal RTC. This port allows user to specify the full 8 bit address (instead of bank0/bank1 indexing) to access the 256 bytes of RTC RAM. |

#### IO073 Alternate RTC DataPort

| Bits | Description                                                                                                                    |
|------|--------------------------------------------------------------------------------------------------------------------------------|
| 7:0  | <b>AlternatRTCDDataPort</b> . Read-write. Reset: 0. This is used with internal RTC in conjunction with <a href="#">IO072</a> . |

#### IO073\_x00 RTC Seconds

| Bits | Description                                                                                                                                                                                                                                                                                                                                    |
|------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 7:0  | <b>Seconds</b> . Read-write. Reset: 0. <a href="#">BCD</a> format. The value range for this register is 00 through 59. If ( <a href="#">IO073_x0B</a> [SET]=1), this register is programmed by software and hardware updating is disabled. If ( <a href="#">IO073_x0B</a> [SET]=0), this register is updated by the RTC logic once per second. |

**IO073\_x01 RTC Seconds Alarm**

| Bits | Description                                                                                                                                                                                                                                                                                                                                                         |
|------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 7:0  | <b>SecondsAlarm: Seconds Alarm.</b> Read-write. Reset: 0. <b>BCD</b> format. If (IO073_x0B[SET]=1), the Seconds Alarm register will never match with IO073_x00 [RTC Seconds]. Else, if (bits [7:6] = 11b) the RTC Seconds Alarm register always matches with RTC Seconds register and causes an RTC alarm event to be generated once per second. See IO073_x0C[AF]. |

**IO073\_x02 RTC Minutes**

| Bits | Description                                                                                                                                                                                                                                                                                   |
|------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 7:0  | <b>Minutes.</b> Read-write. Reset: 0. <b>BCD</b> format. The value range for this register is 00 through 59. If (IO073_x0B[SET]=1), this register programmed by software and hardware updating is disabled. If (IO073_x0B[SET]=0), this register is updated by the RTC logic once per second. |

**IO073\_x03 RTC Minutes Alarm**

| Bits | Description                                                                                                                                                                                                                                                                                                                                                            |
|------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 7:0  | <b>MinutesAlarm: Minutes Alarm.</b> Read-write. Reset: 0. <b>BCD</b> format. If (IO073_x0B[SET]=1), the RTC Minutes Alarm register will never match with IO073_x02 [RTC Minutes]. Else, if (bits [7:6]=11b), the RTC Minutes Alarm register always matches with RTC Minutes register and causes an RTC alarm event to be generated once per minute. See IO073_x0C[AF]. |

**IO073\_x04 RTC Hours**

| Bits | Description                                                                                                                                                                                                                                                                                 |
|------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 7:0  | <b>Hours.</b> Read-write. Reset: 0. <b>BCD</b> format. The value range for this register is 00 through 23. If (IO073_x0B[SET]=1), this register can be set by software and hardware updating is disabled. If (IO073_x0B[SET]=0), this register is updated by the RTC logic once per second. |

**IO073\_x05 RTC Hours Alarm**

| Bits | Description                                                                                                                                                                                                                                                                                                                                                   |
|------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 7:0  | <b>HoursAlarm: Hours Alarm.</b> Read-write. Reset: 0. <b>BCD</b> format. If (IO073_x0B[SET]=1), the RTC Hours Alarm register will never match with IO073_x04 [RTC Hours]. Else, if (bits [7:6] = 11b) the RTC Hours Alarm register always matches with the RTC Hours register and causes an RTC alarm event to be generated once per hour. See IO073_x0C[AF]. |

**IO073\_x06 RTC Day of Week**

| Bits | Description                                                                                                                                                                                                                                                                                                                                              |
|------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 7:0  | <b>DayOfWeek: Day of Week.</b> Read-write. Reset: 0. <b>BCD</b> format. The value range for this register is 01 through 07 (Sunday = 1). Leap year correction is performed by software. If (IO073_x0B[SET]==1), this register is programmed by software and hardware updating is disabled. If (IO073_x0B[SET]==0), this register is updated by hardware. |

**IO073\_x07 RTC Date of Month**

| Bits | Description                                                                                                                                                                                                                                                                                                             |
|------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 7:0  | <b>DateOfMonth: Date of Month.</b> Read-write. Reset: 0. <b>BCD</b> format. The range is 01 through 31. Leap year correction is performed by software. If (IO073_x0B[SET]==1), this register is programmed by software and hardware updating is disabled. If (IO073_x0B[SET]==0), this register is updated by hardware. |

**IO073\_x08 RTC Month**

| Bits | Description                                                                                                                                                                                                                                                                                      |
|------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 7:0  | <b>Month.</b> Read-write. Reset: 0. <b>BCD</b> format. The range is 01 through 12. Leap year correction is performed by software. If (IO073_x0B[SET]=1), this register is programmed by software and hardware updating is disabled. If (IO073_x0B[SET]=0), this register is updated by hardware. |

**IO073\_x09 RTC Year**

| Bits | Description                                                                                                                                                                                                                                                                                                                       |
|------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 7:0  | <b>Year.</b> Read-write. Reset: 0. <b>BCD</b> format. Range is 00 through 99. No leap year correction capability. Leap year correction has to be done by software. If (IO073_x0B[SET]=1), this register is programmed by software and hardware updating is disabled. If (IO073_x0B[SET]=0), this register is updated by hardware. |

**IO073\_x0A RTC Register A**

| Bits | Description                                                                                                                                                                                  |
|------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 7    | <b>UIP: Update In Progress.</b> Read-only. Reset: 0. If (IO073_x0B[SET]=1), UIP is cleared. 1=The update transfer will soon occur. 0=The update transfer will not occur for at least 244 us. |
| 6:5  | Reserved.                                                                                                                                                                                    |

| 4     | <b>DV0: Bank Selection.</b> Read-write. Reset: 0. 0=Select bank 0 when accessing the RTC CMOS RAM space through <a href="#">IO070</a> and <a href="#">IO071</a> . 1=Select bank 1 when accessing the RTC CMOS RAM space through <a href="#">IO070</a> and <a href="#">IO071</a> . The FCH has an alternate way to access the RAM without the use of bank select bit. <a href="#">IO072 [Alternate RTC AddrPort]</a> and <a href="#">IO073 [Alternate RTC DataPort]</a> provides indexed access to the full 256 bytes of RAM.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |      |                                |       |                    |       |                     |       |                    |       |                        |       |                        |       |                        |       |                         |       |                      |       |                     |       |                    |       |                   |       |                  |       |                 |       |               |       |               |       |               |

|------|------------------------------------------------------------------------|
| 7:0  | <b>DmaWriteMask.</b> Read-write. Reset: 0. DMA2 channel mask register. |

**IO0D6 Dma\_WriteMode**

| Bits | Description                                                    |
|------|----------------------------------------------------------------|
| 7:0  | <b>DmaWriteMode.</b> Read-write. Reset: 0. DMA2 mode register. |

**IO0D8 Dma\_Clear**

| Bits | Description                                                            |
|------|------------------------------------------------------------------------|
| 7:0  | <b>DmaClear.</b> Read-write. Reset: 0. Channel 4-7 clear byte pointer. |

**IO0DA Dma\_MasterClr**

| Bits | Description                                                                                                     |
|------|-----------------------------------------------------------------------------------------------------------------|
| 7:0  | <b>DmaMasterClear</b> . Read-write. Reset: 0. Write: Channel 4-7 DMA master clear. Read: Intermediate register. |

**IO0DC Dma\_ClrMask**

| Bits | Description                                                           |
|------|-----------------------------------------------------------------------|
| 7:0  | <b>DmaClrMask</b> . Read-write. Reset: 0. Channel 4-7 DMA clear mask. |

**IO0DE Dma\_AllMask**

| Bits | Description                                                   |
|------|---------------------------------------------------------------|
| 7:0  | <b>DmaAllMask</b> . Read-write. Reset: 0. DMA2 mask register. |

**IO0F0 NCP Error**

Writes to this port assert IGNNE# if FERR# is true. If FERR# is false, writes to this port do not assert IGNNE#. The first write will set WarmBoot.

| Bits | Description                                                                                                                                                                                                                                                                                                                      |
|------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 7    | <b>WarmBoot</b> . Read; write-once. Cold reset: 0. Warm or cold boot indicator. 0=Cold. 1=Warm. This bit is set when any value is written to this register. The BIOS reads (tests) this register early in to POST process, then writes the register, thus setting WarmBoot. On subsequent warm boots, this flag will remain set. |
| 6:0  | Reserved.                                                                                                                                                                                                                                                                                                                        |

| 7:0  | <b>HPET</b> . See: <a href="#">IOC01_x0A</a> [HPET]. |

### IOC01\_x0[7F:C] PCI Interrupt Map

| Bits | Description                                                                                                                                                                                                                                                                                                                                                                                                                            |
|------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 7:5  | Reserved. Read-write. Reset: 3.                                                                                                                                                                                                                                                                                                                                                                                                        |
| 4:0  | <b>Pci2IntrMap</b> . Read-write. Reset: 1Fh. If ( <a href="#">IOC00</a> [PciIntrApic]==1), then Pci2IntrMap specifies the APIC interrupt number that the corresponding PCI interrupt maps to. If ( <a href="#">IOC00</a> [PciIntrApic]==0), then Pci2IntrMap specifies the PIC interrupt number that the corresponding PCI interrupt maps to. See <a href="#">IOC00</a> [ <a href="#">Pci_Intr_Index</a> ] for the PCI interrupt list. |

### IOC14 Pci\_Error

| Bits | Description                                                                                                                                                                                  |
|------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 7:4  | Reserved.                                                                                                                                                                                    |
| 3    | <b>PerrNmi</b> . Read-write. Reset: 1. Enable NMI generation from PERR#. 0=Enable. 1=Disable.                                                                                                |
| 2    | <b>SerrNmi</b> . Read-write. Reset: 1. Enable NMI generation from SERR#. 0=Enable. 1=Disable.                                                                                                |
| 1    | <b>PerrNmiStatus</b> . Read-only. Reset: X. 1=NMI generation is enabled and PERR# is asserted due to a PCI data parity error. This bit is cleared by writing 1 to <a href="#">IO061</a> [2]. |
| 0    | <b>SerrNmiStatus</b> . Read-only. Reset: X. 1=NMI generation is enabled and SERR# is asserted due to a PCI error. This bit is cleared by writing 1 to <a href="#">IO061</a> [2].             |

**IOCD0 PM2\_Index**

| Bits | Description                                                                                                                                                                                                    |
|------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 7:0  | <b>Pm2Index: Power management 2 index register.</b> Read-write. Reset: 0. This register specifies the index of the power management 2 register. See <a href="#">Power Management Block 2 (PM2) Registers</a> . |

**IOCD1 PM2\_Data**

| Bits | Description                                                                                                                                                                                                                                                     |
|------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 7:0  | <b>Pm2Data: Power management 2 data register.</b> Read-write. Reset: 0. This register specifies the data read from/written to the power management 2 register pointed by <a href="#">IOCD0</a> . See <a href="#">Power Management Block 2 (PM2) Registers</a> . |

**IOCD4 BIO SRAMIndex**

| Bits | Description                                                                                                                                                                                                  |
|------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 7:0  | <b>BiosRamIndex: BIOS RAM index register.</b> Read-write. Reset: 0. This register specifies the index in the 256-byte BIOS RAM. Data in this RAM is preserved until RSMRST# is asserted or S5 power is lost. |

**IOCD5 BIO SRAM Data**

| Bits | Description                                                                                                                                                             |
|------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 7:0  | <b>BiosRamData: BIOS RAM data register.</b> Read-write. Reset: 0. This register specifies the data read from/written to the BIOS RAM pointed by <a href="#">IOCD4</a> . |

**IOCD6 PM\_Index**

| Bits | Description                                                                                                                                                                                                |
|------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 7:0  | <b>PmIndex: Power management index register.</b> Read-write. Reset: 0. This register specifies the index of the power management register. See <a href="#">3.26.13 [Power Management (PM) Registers]</a> . |

**IOCD7 PM\_Data**

| Bits | Description                                                                                                                                                                                                                                                 |
|------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 7:0  | <b>PmData: Power management data register.</b> Read-write. Reset: 0. This register specifies the data read from/written to the power management register pointed by <a href="#">IOCD6</a> . See <a href="#">3.26.13 [Power Management (PM) Registers]</a> . |

**IOCF9 System Reset Register**

This register can be accessed through [PMxC5 \[CF9 Shadow\]](#).

| Bits | Description                                                                                                       |
|------|-------------------------------------------------------------------------------------------------------------------|
| 7:4  | Reserved.                                                                                                         |
| 3    | <b>FullRst.</b> Read-write. Reset: 0. 0=Assert reset signals only. 1=Place system in S5 state for 3 to 5 seconds. |
| 2    | <b>RstCmd.</b> Read-write; Cleared-by-hardware. Reset: 0. 1=Generate reset as specified by FullRst and SysRst.    |

### 3.26.2 AB Configuration Registers (Scallion)

AB Configuration registers are accessed indirectly through [ABx00 \[AB Index Register\]](#) and [ABx04 \[AB Data Register\]](#). The [ABx00/ABx04](#) register pair is located in IO address space as defined by [PMxE0](#).

#### ABx00 AB Index Register

| Bits      | Description                                                                                                                                                                                                                                                                                                                                                                                            |      |            |           |          |      |                                    |      |          |

### D11F0x08 Revision ID/Class Code

SATA controller has different values for Subclass Code and ProgramIF[7:0] depending on its operating mode.

**Table 230: SATA Controller Subclass Code and ProgramIF Settings**

| Subclass Code | ProgramIF[7:0] | Controller Type |
|---------------|----------------|-----------------|
| 01            | 8Fh/8Ah        | IDE             |
| 06            | 01             | AHCI            |

| Bits        | Description                                                                                                                                                                                                                                                                                                                                                                                                   |             |                   |    |                           |    |                        |

#### D11F0x24 AHCI Base Address (BAR5)

| Bits  | Description                                                                                                                                                                                                  |
|-------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31:10 | <b>AHCIBaseAddress: AHCI Base Address[31:10].</b> Read-write. Reset: 0. Specifies base address[31:10] of the AHCI control register space. See <a href="#">3.26.3.3 [SATA Memory Mapped AHCI Registers]</a> . |
| 9:1   | Reserved.                                                                                                                                                                                                    |
| 0     | <b>ResourceTypeIndicator: Resource Type Indicator.</b> Value: 0. 0=Base address field in this register maps to the memory space.                                                                             |

#### D11F0x2C Subsystem ID and Subsystem Vendor ID

| Bits  | Description                                                                |
|-------|----------------------------------------------------------------------------|
| 31:16 | <b>SubsystemID: Subsystem ID.</b> Write-once; read. Reset: 0.              |
| 15:0  | <b>SubsystemVendorID: Subsystem Vendor ID.</b> Write-once; read. Reset: 0. |

#### D11F0x34 Capabilities Pointer

| Bits | Description                                                                                                                                                                                               |
|------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31:8 | Reserved.                                                                                                                                                                                                 |
| 7:0  | <b>CapabilitiesPointer: Capabilities Pointer.</b> IF ( <a href="#">D11F0x40</a> [SubclassCodeWriteEnable]) THEN Read-write. ELSE Read-only. ENDIF. Reset: 60h. The first pointer of the Capability block. |

#### D11F0x3C Interrupt Line

| Bits  | Description                                                                                                                                                   |
|-------|---------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31:24 | <b>MaximumLatency: Maximum Latency.</b> Value: 0. Specifies the Maximum Latency time required before the SATA controller can start an access as a bus-master. |

|       |                                                                                                                                                                                                     |
|-------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 23:16 | <b>MinimumGrant: Minimum Grant.</b> Value: 0. Specifies the desired settings for how long of a burst the SATA controller needs. The value specifies a period of time in units of 1/4 microseconds.  |
| 15:8  | <b>InterruptPin: Interrupt Pin.</b> Value: 1.                                                                                                                                                       |
| 7:0   | <b>InterruptLine: Interrupt Line.</b> Read-write. Reset: 0. Identifies which input on the interrupt controller this function's PCI interrupt request pin as specified in InterruptPin is routed to. |

### D11F0x40 Misc Control

| Bits  | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |     |            |     |                  |     |                  |       |          |

**D11F0x7C IDP Data Register**

| Bits | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
|------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31:0 | <b>IDPData: IDP Data.</b> Read-write. Reset: 0h. This register is a window through which data is read or written to the memory mapped AHCI register pointed to by the <a href="#">D11F0x78 [IDP Index Register]</a> . See <a href="#">3.26.3.3 [SATA Memory Mapped AHCI Registers]</a> . This is not a physical register, the default value for this field is 0000_0000h, once software programs a valid address in <a href="#">D11F0x78 [IDP Index Register]</a> , it switches to the register value which IDPIndex pointing to. The AHCI registers can be accessed both through <a href="#">D11F0x24 [AHCI Base Address (BAR5)]</a> and through this index/data pair. |

## D11F0x98 PHY Fine Tune PortX GenX Setting

This register is both port and generation speed sensitive. Software must program [D11F0x80\[PN\]](#) to select port and [D11F0x80\[GEN\]](#) to select generation speed before accessing this register.

| Bits             | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |     |            |     |             |       |                                                                                                  |       |                    |                  |                   |       |    |       |    |       |    |

| 1:0 | <b>PortXBistPortSelect: PortX BIST Port Select.</b> Read-write. Reset: 0. This register is bit significant. When the bit is 1, it indicates the port that software will read from/write to during link BIST. For reads, the port is determined by the last significant bit with value 1 in this field. For writes, the port(s) is determined by the any bit with value 1 in this field. This register must be programmed before reading back from <a href="#">D11F0xB0</a> , or writing to/reading from <a href="#">D11F0xB4</a> to avoid reading from/written to an un-expected port. |

#### D11F0xBC T-Mode BIST Transit Pattern DW1

| Bits | Description                                                                                                                                                                           |

| 15:8 | Reserved.                                                                                                                                                                                                                                                                                                              |
| 7:0  | <b>Count: PCI Target Control Timeout Count.</b> Read-write. Reset: 80h. This field specifies the PCI target control timeout count used to clear any stale target commands to the host controller. Granularity is 15.5 us (Timeout Counter = Count * 15.5 us). The counter is disabled if the count is programmed to 0. |

**3.26.3.2 SATA IO Registers****3.26.3.2.1 IDE Compatibility Mode and Native Mode (BAR0, BAR1, BAR2, BAR3) Registers**

See 3.1 [Register Descriptions and Mnemonics] for a description of the register naming convention.

Compatibility Mode is selected by [D11F0x08](#)[ProgramIF[0], ProgramIF[2]]==0 respectively. In Compatibility Mode the IO address is forced to the legacy compatible address. The same group of registers can be specified as Native Mode by [D11F0x08](#)[ProgramIF[0], ProgramIF[2]]==1 respectively. In Native Mode, the IO address is specified by [D11F0x10](#), [D11F0x14](#), [D11F0x18](#) and [D11F0x1C](#) (BAR0, BAR1, BAR2, BAR3).

**Table 231: IDE Compatibility Mode and Native Mode Address Mapping**

| Compatibility Mode:<br>Interface, IO Address | Native Mode:<br>Interface, BAR+Offset | Read Function    | Write Function | Register    |

**IDE\_BMx0[C,4] Descriptor Table Pointer**

Primary and Secondary Bus Master IDE Descriptor Table Pointer register.

| Bits | Description                                                                                                                      |
|------|----------------------------------------------------------------------------------------------------------------------------------|
| 31:2 | <b>DescriptorTableBaseAddress: Descriptor Table Base Address.</b> Read-write. Reset: 0. These bits correspond to Address [31:2]. |
| 1:0  | Reserved.                                                                                                                        |

**3.26.3.3 SATA Memory Mapped AHCI Registers**

These are the AHCI memory mapped registers. The base address is defined by [D11F0x24 \[AHCI Base Address \(BAR5\)\]](#). See section [3.1 \[Register Descriptions and Mnemonics\]](#) for a description of the register naming convention.

### 3.26.3.3.1 Generic Host Control Registers

#### SATAx00 HBA Capabilities (CAP)

| Bits        | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |      |            |       |          |       |                 |       |                        |       |                                 |             |          |
|-------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------|------------|-------|----------|-------|-----------------|-------|------------------------|-------|---------------------------------|-------------|----------|
| 31          | <b>S64A: Supports 64-bit Addressing.</b> Read-only. Reset: 1. Indicates whether HBA can access 64-bit data structures. 1=HBA will make the 32-bit upper bits of the port DMA Descriptor, the PRD Base, and each PRD entry read/write. 0=These bits are read-only and treated as 0s by the HBA.                                                                                                                                                                                                                                                                                                                                            |      |            |       |          |       |                 |       |                        |       |                                 |             |          |
| 30          | <b>SNCQ: Supports Native Command Queuing.</b> Read-only. Reset: 1. Indicates whether HBA supports Serial ATA native command queuing. 1=HBA can handle DMA Setup FISes natively, and can handle the auto-activate optimization through that FIS. 0=Native command queuing is not supported and software should not issue any native command queuing commands. Writing <a href="#">SATAxFC[CFG_CAP_SNCQ]</a> updates this bit.                                                                                                                                                                                                              |      |            |       |          |       |                 |       |                        |       |                                 |             |          |
| 29          | <b>SSNTF: Supports SNotification Register.</b> Read-only. Reset: 1. 1=HBA supports the <a href="#">SATAx1[B,3]C [Port 1,0 SNotification (PxSNTF)]</a> register and its associated functionality. 0=HBA does not support the <a href="#">SATAx1[B,3]C [Port 1,0 SNotification (PxSNTF)]</a> register and its associated functionality. Writing <a href="#">SATAxFC[CFG_CAP_SSNTF]</a> updates this bit.                                                                                                                                                                                                                                    |      |            |       |          |       |                 |       |                        |       |                                 |             |          |
| 28          | <b>SMPS: Supports Mechanical Presence Switch.</b> Read-only. | 31   | <b>AE: AHCI Enable.</b> Read-write. Reset: 0. 1=Indicates that communication to HBA shall be via AHCI mechanisms. 0=Software shall only communicate with HBA using legacy mechanisms; FISes are not posted to memory, and no commands are sent via AHCI mechanisms. This can be used by an HBA that supports both legacy mechanisms and AHCI to know when the HBA is running under an AHCI driver. Software shall set this bit to 1 before accessing other AHCI registers.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| 30:3 | Reserved.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| 2    | <b>MRSM: MSI Revert to Single Message.</b> Read-only. Reset: 0. 1=HBA requested more than one MSI vector but has reverted to using the first vector only. 0=HBA has not reverted to single MSI mode (i.e., hardware is already in single MSI mode, software has allocated the number of messages requested, or hardware is sharing interrupt vectors if <a href="#">D11F0x50[MME]&lt;D11F0x50[MMC]</a> ). HBA may revert to single MSI mode when the number of vectors allocated by the host is less than the number requested. This bit shall only be set to 1 when the following conditions hold: <ul style="list-style-type: none"> <li>• <a href="#">D11F0x50[MSIE]=1</a> (MSI is enabled)</li> <li>• <a href="#">D11F0x50MMC]&gt;0</a> (multiple messages requested)</li> <li>• <a href="#">D11F0x50MME]&gt;0</a> (more than one message allocated)</li> <li>• <a href="#">D11F0x50MME]!=D11F0x50[MMC]</a> (messages allocated not equal to number requested)</li> </ul> When this bit is set to 1, single MSI mode operation is in use and software is responsible for clearing bits in the IS register to clear interrupts. This bit shall be cleared to 0 by hardware when any of the four conditions stated is false. This bit is also cleared to 0 when <a href="#">D11F0x50[MSIE] = 1</a> and <a href="#">D11F0x50[MME] = 0h</a> . In this case, hardware has been programmed to use single MSI mode, and is not “reverting” to that mode. |
| 1    | <b>IE: Interrupt Enable.</b> Read-write. Reset: 0. This global bit enables interrupts from HBA. 0=All interrupt sources from all ports are disabled. 1=Interrupts are enabled.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| 0    | <b>HR: HBA Reset.</b> Read; write-1-only; cleared-by-hardware. Reset: 0. When set by software, this bit causes an internal reset of HBA. All state machines that relate to data transfers and queuing shall return to an idle condition, and all ports shall be re-initialized via COMRESET (if staggered spin-up is not supported). If staggered spin-up is supported, then it is the responsibility of software to spin-up each port after the reset has completed. When HBA has performed the reset action, it shall reset this bit to 0. For a description on which bits are reset when this bit is set, see AHCI spec, section 10.4.3.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |

**SATAx08 Interrupt Status (IS)**

| Bits | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |     |            |     |                              |     |                              |     |     |      |                               |

| 15:0  | <p><b>MNR: Minor Version Number.</b> IF (<a href="#">D11F0x40[SubclassCodeWriteEnable]</a> == 1) THEN Read-write. ELSE Read-only. ENDIF. Reset: 300h. Indicates the minor version is 10.</p> |

**SATAx14 Command Completion Coalescing Control (CCC\_CTL)**

| Bits  | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
|-------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31:16 | <p><b>TV: Timeout Value.</b> Read-write. Reset: 1. The timeout value is specified in 1 millisecond intervals. The timer accuracy shall be within 5%. hCccTimer is loaded with this timeout value. hCccTimer is only decremented when commands are outstanding on selected ports. The HBA will signal a CCC interrupt when hCccTimer has decremented to 0. hCccTimer is reset to the timeout value on the assertion of each CCC interrupt. A timeout value of 0 is reserved.</p> |

|      |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
|------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 15:8 | <b>CC: Command Completions.</b> Read-write. Reset: 1. Specifies the number of command completions that are necessary to cause a CCC interrupt. The HBA has an internal command completion counter, hCccComplete that is incremented by one each time a selected port has a command completion. When hCccComplete is equal to the command completions value, a CCC interrupt is signaled. The internal command completion counter is reset to 0 on the assertion of each CCC interrupt. 0=Disable CCC interrupts being generated based on the number of commands completed, i.e. CCC interrupts are only generated based on the timer in this case. |
| 7:3  | <b>INT: CCC Interrupt.</b> Read-only. Reset: 2h. Specifies the interrupt used by the Command Completion Coalescing (CCC) feature. This interrupt must be marked as unused in <a href="#">SATAx0C [Ports Implemented (PI)]</a> by having the corresponding bit being set to 0. Thus, the CCC interrupt corresponds to the interrupt for an un-implemented port on the controller. When a CCC interrupt occurs, the corresponding bit in <a href="#">SATAx08 [Interrupt Status (IS)]</a> shall be asserted to 1. This field also specifies the interrupt vector used for MSI.                                                                        |
| 2:1  | Reserved.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| 0    | <b>EN: CCC CTL Enable.</b> Read-write. Reset: 0. 0=The Command Completion Coalescing (CCC) feature is disabled and no CCC interrupts are generated. 1=The CCC feature is enabled and CCC interrupts may be generated based on timeout or command completion conditions. Software shall only change the contents of the TV and CC fields in this register when this bit is cleared to 0. On transition of this bit from 0 to 1, any updated values for the TV and CC fields shall take effect.                                                                                                                                                      |

### SATAx18 Command Completion Coalescing Ports (CCC\_PORTS)

| Bits | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
|------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31:0 | <b>PRT: Ports.</b> Read-write. Reset: 0. This register is bit significant. Each bit corresponds to a particular port, where bit 0 corresponds to port 0. If a bit is set to 1, the corresponding port is part of the command completion coalescing feature. If a bit is cleared to 0, the port is not part of the command completion coalescing feature. Bits set to 1 in this register must also have the corresponding bit set to 1 in the <a href="#">SATAx0C [Ports Implemented (PI)]</a> . An updated value for this field shall take effect within one timer increment (1 millisecond). |

### SATAx1C Enclosure Management Location (EM\_LOC)

| Bits  | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
|-------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31:16 | <b>OFST: Offset.</b> IF ( <a href="#">SATAxFC[CFG_CAP_EMS]</a> ==0) THEN Value: 0000h. ELSE Value: 0140h. ENDIF. Specifies the offset of the message buffer in doublewords from the beginning of BAR5 defined by <a href="#">D11F0x24</a> .                                                                                                                                                                                                                                        |
| 15:0  | <b>SZ: Buffer Size.</b> IF ( <a href="#">SATAxFC[CFG_CAP_EMS]</a> ==0) THEN Value: 0000h. ELSE Value: 0040h. ENDIF. Specifies the size of the transmit message buffer area in doublewords. If both transmit and receive buffers are supported, then the transmit buffer begins at <a href="#">SATAx1C[OFST]*4</a> and the receive buffer directly follows it. If both transmit and receive buffers are supported, both buffers are of the size indicated in the Buffer Size field. |

**SATAx20 Enclosure Management Control (EM\_CTL)**

| Bits  | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
|-------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31:28 | Reserved.                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| 27    | <b>ATTR_PM: Port Multiplier Support.</b> Read-only. Reset: 0. 1=The HBA supports enclosure management messages for devices attached via a Port Multiplier. 0=The HBA does not. When cleared to 0, software should use the Serial ATA enclosure management bridge that is built into many Port Multipliers for enclosure services with these devices. For more information on Serial ATA enclosure management bridges, refer to the Serial ATA Revision 2.6 specification. |
| 26    | <b>ATTR_ALHD: Activity LED Hardware Driven.</b> Read-only. Reset: 0. 1=The HBA drives the activity LED for the LED message type in hardware and does not utilize software settings for this LED. The HBA does not begin transmitting the hardware based activity signal until after software has written CTL_TM to 1 after a reset condition.                                                                                                                             |

Reset: 0. 1=The HBA supports the BIOS/OS handoff mechanism as defined in AHCI 1.2 section 10.6 and the HBA has implemented <a href="#">SATAx28 [BIOS/OS Handoff Control and Status (BOHC)]</a> . 0=The HBA does not support the BIOS/OS handoff mechanism and <a href="#">SATAx28 [BIOS/OS Handoff Control and Status (BOHC)]</a> is not implemented.                                                |

**SATAx28 BIOS/OS Handoff Control and Status (BOHC)**

| Bits | Description                                                                                                                                                                                                                         |
|------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31:5 | Reserved.                                                                                                                                                                                                                           |
| 4    | <b>BB: BIOS Busy.</b> Read-write. Reset: 0. This bit is used by the BIOS to indicate that it is busy cleaning up for ownership change.                                                                                              |
| 3    | <b>OOC: OS Ownership Change.</b> Read; write-1-to-clear. Reset: 0. This bit is set to 1 when the OOS bit transitions from 0 to 1.                                                                                                   |
| 2    | <b>SOOE: SMI on OS Ownership Change Enable.</b> Read-write. Reset: 0. 1=Enables an SMI when the OOC bit has been set to 1.                                                                                                          |
| 1    | <b>OOS: OS Owned Semaphore.</b> Read-write. Reset: 0. The system software sets this bit to request ownership of the HBA controller. Ownership is obtained when this bit reads 1 and the BOS bit reads 0.                            |
| 0    | <b>BOS: BIOS Owned Semaphore.</b> Read-write. Reset: 0. The BIOS sets this bit to establish ownership of the HBA controller. BIOS will clear this bit in response to a request for ownership of the HBA by system software via OOS. |

**3.26.3.3.2 Port Control Registers**

The following registers configure the SATA ports and are implemented per port. Each port shall have the same

register mapping. Port 0 starts at 100h. Port 1 starts at 180h. An algorithm to determine the offset is as follows:  
 Port offset = 100h + (Asserted Bit Position in [SATAx0C \[Ports Implemented \(PI\)\]](#) \* 80h).

#### **SATAx1[8,0] Port 1,0 Command List Base Address (PxCLB)**

| Bits  | Description                                                                                                                                                                                                                                                                                                                                         |
|-------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31:10 | <b>CLB[31:10]: Command List Base Address [31:10].</b> Read-write. Reset: 0. Specifies the lower 32 bits of the physical base address for the command list for this port. This base address is used by HBA to fetch commands to execute. The structure pointed to by this address range is 1K-bytes in length. This address must be 1K-byte aligned. |
| 9:0   | Reserved.                                                                                                                                                                                                                                                                                                                                           |

#### **SATAx1[8,0]4 Port 1,0 Command List Base Upper Address (PxCLBU)**

| Bits | Description                                                                                                                                                                                                                    |
|------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31:0 | <b>CLBU: Command List Base Address Upper.</b> Read-write. Reset: 0. Specifies the upper 32 bits of the physical base address for the command list for this port. If 64-bit addressing is not supported, this register reads 0. |

#### **SATAx1[8,0]8 Port 1,0 FIS Base Address (PxFB)**

| Bits | Description                                                                                                                                                                                                                                                                  |
|------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31:8 | <b>FB[31:8]: FIS Base Address [31:8].</b> Read-write. Reset: 0. Specifies the lower 32 bits of the physical base address for the received FISes for this port. The structure pointed to by this address range is 256 bytes in length. This address must be 256-byte aligned. |
| 7:0  | Reserved.                                                                                                                                                                                                                                                                    |

#### **SATAx1[8,0]C Port 1,0 FIS Base Address Upper (PxFBU)**

| Bits | Description                                                                                                                                                                                                            |
|------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31:0 | <b>FBU: FIS Base Address Upper.</b> Read-write. Reset: 0. Specifies the upper 32 bits of the physical base address for the received FISes for this port. If 64-bit addressing is not supported, this register reads 0. |

#### **SATAx1[9,1]0 Port 1,0 Interrupt Status (PxIS)**

| Bits | Description                                                                                                                                                                                                                                                                                                                                          |
|------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31   | <b>CPDS: Cold Port Detect Status.</b> Read; write-1-to-clear. Reset: 0. 1=The device status has changed as detected by the cold presence detection logic. This bit can be set due to either a non-connected port receiving a device, or a connected port having its device removed. This bit is only valid if <a href="#">SATAx1[9,1]8[CPD]</a> ==1. |
| 30   | <b>TFES: Task File Error Status.</b> Read; write-1-to-clear. Reset: 0. 1=The error bit at bit [0] of the status field in the received FIS is set to 1 when the status register is updated by the device.                                                                                                                                             |

|      |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |

| 8h    | DevSleep: This shall cause the HBA to assert the DEVSLP signal associated with the port; the HBA shall ignore the Device Sleep Idle Timeout value specified by PxDEVSLP.DITO. Software shall only request DevSleep when the interface is in an idle state (i.e. PxCI is cleared to 0h and PxSACT are cleared to 0h); if CAP2.SDS is cleared to '0' or if the interface is not idle at the time the register is written, then the HBA shall not assert the DEVSLP signal and the interface remains in its current state. If CAPS.SDS is set to '1', CAP2.DESO is set to '1', and PxSSTS.IPM is not set to '6h', then the HBA shall not assert the DEVSLP signal and the interface shall remain in its current state. Additionally, the HBA shall not assert the DEVSLP signal until PHYRDY has been achieved (after a previous de-assertion).                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |      |            |       |          |    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |    |          |    |                                                                                                                                                                                              |       |          |    |                                                                                                                                                                                              |    |                                                                                                  |    |                                                                                                                                                                                                           |

Reset: 0. 1=The command list DMA engine for the port is running.                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| 14 | <b>FR: FIS Receive Running.</b> Read-only. Reset: 0. 1=The FIS Receive DMA engine for the port is running.                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| 13 | <b>MPSS: Mechanical Presence Switch State.</b> Read-only. Reset: 1. This bit reports the state of a mechanical presence switch attached to this port. If <a href="#">SATAx00[SMPS]</a> ==1 and the mechanical presence switch is closed then this bit is cleared to 0. If <a href="#">SATAx00[SMPS]</a> ==1 and the mechanical presence switch is open then this bit is set to 1. If <a href="#">SATAx00[SMPS]</a> ==0 then this bit is cleared to 0. Software should only use this bit if (( <a href="#">SATAx00[SMPS]</a> ==1) && ( <a href="#">SATAx1[9,1]8[MPSP]</a> ==1)). |

|      |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
|------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 12:8 | <b>CCS: Current Command Slot.</b> Read-only; updated-by-hardware. Reset: 0. This field is valid if <a href="#">SATAx1[9,1]8[ST]==1</a> and shall be set to the command slot value of the command that is currently being issued by the HBA. When <a href="#">SATAx1[9,1]8[ST]</a> transitions from 1 to 0, this field shall be reset to 0. After <a href="#">SATAx1[9,1]8[ST]</a> transitions from 0 to 1, the highest priority slot to issue from next is command slot 0. After the first command has been issued, the highest priority slot to issue from next is CCS+1. For example, after the HBA has issued its first command, if CCS==0 and <a href="#">SATAx1[B,3]8==3</a> , the next command that will be issued is from command slot 1.                                                               |
| 7:5  | Reserved.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| 4    | <b>FRE: FIS Receive Enable.</b> Read-write. Reset: 0. 1=The HBA may post the received FISes into the FIS receive area pointed to by <a href="#">SATAx1[8,0]8 [Port 1,0 FIS Base Address (PxFB)]</a> (and <a href="#">SATAx1[8,0]C [Port 1,0 FIS Base Address Upper (PxFBU)]</a> for 64-bit HBAs). 0=Received FISes are not accepted by the HBA, except for the first D2H register FIS after the initialization sequence, and no FISes are posted to the FIS receive area. System software must not set this bit until <a href="#">SATAx1[8,0]8</a> (and <a href="#">SATAx1[8,0]C</a> for 64-bit) have been programmed with a valid pointer to the FIS receive area. If software wishes to move the base, this bit must first be cleared, and software must wait for the FR bit in this register to be cleared. |
| 3    | <b>CLO: Command List Override.</b> Read; write-1-only; cleared-by-hardware. Reset: 0. Setting this bit to 1 causes <a href="#">SATAx1[A,2]0[STS[7], STS[3]]</a> to be cleared to 0. This allows a software reset to be transmitted to the device regardless of whether the BSY and DRQ bits are still set in the <a href="#">SATAx1[A,2]0[STS]</a> register. The HBA sets this bit to 0 when <a href="#">SATAx1[A,2]0[STS[7], STS[3]]</a> have been cleared to 0. This bit shall only be set to 1 immediately prior to setting <a href="#">SATAx1[9,1]8[ST]</a> to 1 from a previous value of 0. Setting this bit to 1 at any other time is not supported and will result in indeterminate behavior. Software must wait for CLO to be cleared to 0 before setting <a href="#">SATAx1[9,1]8[ST]</a> to 1.       |
| 2    | <b>POD: Power On Device.</b> IF ( <a href="#">SATAx1[9,1]8[CPD]==1</a> ) THEN Read-write. ELSE Read-only. ENDIF. Reset: 1. This bit is read/write for HBAs that support cold presence detection on this port as indicated by <a href="#">SATAx1[9,1]8[CPD]==1</a> . 1=HBAs does not support cold presence detect and the HBA sets the state of a pin on the HBA to 1 so that it may be used to provide power to a cold-presence detectable port.                                                                                                                                                                                                                                                                                                                                                               |
| 1    | <b>SUD: Spin-Up Device.</b> IF ( <a href="#">SATAx00[SSS]==1</a> ) THEN Read-write. ELSE Read-only. ENDIF. Reset: 1. This bit is read/write for HBAs that support staggered spin-up via <a href="#">SATAx00[SSS]==1</a> . 1=HBAs does not support staggered spin-up. On an edge detect from 0 to 1, the HBA shall start a COMRESET initialization sequence to the device. Clearing this bit does not cause any OOB signal to be sent on the interface. When this bit is cleared to 0 and <a href="#">SATAx1[A,2]C[DET]==0</a> the HBA will enter listen mode.                                                                                                                                                                                                                                                  |
| 0    | <b>ST: Start.</b> Read-write. Reset: 0. 1=The HBA may process the command list. 0=The HBA may not process the command list. Whenever this bit is changed from 0 to 1, the HBA starts processing the command list at entry 0. Whenever this bit is changed from a 1 to a 0, <a href="#">SATAx1[B,3]8</a> is cleared by the HBA upon the HBA putting the controller into an idle state. This bit will only be set to 1 by software after <a href="#">SATAx1[9,1]8[FRE]</a> has been set to 1.                                                                                                                                                                                                                                                                                                                    |

Contains diagnostic error information for use by diagnostic software in validating correct operation or isolating failure modes:                                                                                                                              |
| <u>Bit</u> | <u>Definition</u>                                                                                                                                                                                                                                                                                                         |
| [15:11]    | Reserved                                                                                                                                                                                                                                                                                                                  |
| [10]       | Exchanged (X). Indicates a COMINIT signal was received. This bit is reflected in <a href="#">SATAx1[9,1]0[PCS]</a> .                                                                                                                                                                                                      |
| [9]        | Unknown FIS Type (F). Indicates that one or more FISs were received by the Transport layer with good CRC, but had a type field that was not recognized/known.                                                                                                                                                             |
| [8]        | Transport state transition error (T). Indicates that an error has occurred in the transition from one state to another within the Transport layer since the last time this bit was cleared. This bit is always 0 in the current implementation.                                                                           |
| [7]        | Link Sequence Error (S). Indicates that one or more Link state machine error conditions was encountered. The Link Layer state machine defines the conditions under which the link layer detects an erroneous transition. This bit is always 0 in the current implementation.                                              |
| [6]        | Handshake Error (H). Indicates that one or more R_ERR handshake responses were received in response to frame transmission. Such errors may be the result of a CRC error detected by the recipient, a disparity or 8b/10b decoding error, or other error condition leading to a negative handshake on a transmitted frame. |
| [5]        | CRC Error (C). Indicates that one or more CRC errors occurred with the Link Layer.                                                                                                                                                                                                                                        |
| [4]        | Disparity Error (D). This field is not used by AHCI. This bit is always 0 in the current implementation.                                                                                                                                                                                                                  |
| [3]        | 10B to 8B Decode Error (B). Indicates that one or more 10B to 8B decoding errors has occurred.                                                                                                                                                                                                                            |
| [2]        | Comm Wake (W). Indicates that a Comm Wake signal was detected by the PHY.                                                                                                                                                                                                                                                 |
| [1]        | Phy Internal Error (I). Indicates that the PHY detected some internal error. This bit is always 0 in the current implementation.                                                                                                                                                                                          |
| [0]        | PhyRdy Change (N). Indicates that the PhyRdy signal changed state. This bit is reflected in the <a href="#">SATAx1[9,1]0[PRCS]</a> bit.                                                                                                                                                                                   |

|            |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |

| <u>Bit</u> | <u>Definition</u>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| [15:12]    | Reserved.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| [11]       | Internal Error (E). The host bus adapter experienced an internal error that caused the operation to fail and may have put the host bus adapter into an error state. The internal error may include a master or target abort when attempting to access system memory, an elasticity buffer overflow, a primitive mis-alignment, a synchronization FIFO overflow, and other internal error conditions. Typically, when an internal error occurs, a non-fatal or fatal status bit in <a href="#">SATAx1[9,1]0</a> register will also be set to give software guidance on the recovery mechanism required. |
| [10]       | Protocol Error (P). A violation of the Serial ATA protocol was detected.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| [9]        | Persistent Communication or Data Integrity Error (C). A communication error that was not recovered occurred and is expected to be persistent. Persistent communication errors may arise from faulty interconnect with the device, from a device that has been removed or has failed, or a number of other causes.                                                                                                                                                                                                                                                                                      |
| [8]        | Transient Data Integrity Error (T). A data integrity error occurred that was not recovered by the interface. This bit is set upon any error when a Data FIS is received, including reception FIFO overflow, CRC error, or 10b/8b decoding error.                                                                                                                                                                                                                                                                                                                                                       |
| [7:2]      | Reserved.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| [1]        | Recovered Communications Error (M). Communications between the device and host was temporarily lost but was re-established. This can arise from a device temporarily being removed, from a temporary loss of PHY synchronization, or from other causes and may be derived from the PhyNRdy signal between the PHY and Link layers.                                                                                                                                                                                                                                                                     |
| [0]        | Recovered Data Integrity Error (I). A data integrity error occurred that was recovered by the interface through a retry operation or other recovery action. This bit is set upon any error when a Data FIS is received, including reception FIFO overflow, CRC error, or 10b/8b decoding error.                                                                                                                                                                                                                                                                                                        |

#### SATAx1[B,3]4 Port 1,0 Serial ATA Active (PxSACT)

| Bits | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
|------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31:0 | <b>DS: Device Status.</b> Read; write-1-only; cleared-by-hardware. Reset: 0. This field is bit significant. Each bit corresponds to the TAG and command slot of a native queued command, where bit 0 corresponds to TAG 0 and command slot 0. This field is set by software prior to issuing a native queued command for a particular command slot. Prior to writing <a href="#">SATAx1[B,3]8</a> TAG to 1, software will set DS TAG to 1 to indicate that a command with that TAG is outstanding. The device clears bits in this field by sending a Set Device Bits FIS to the host. The HBA clears bits in this field that are set to 1 in the SActive field of the Set Device Bits FIS. The HBA only clears bits that correspond to native queued commands that have completed successfully.<br>Software should only write to this field when <a href="#">SATAx1[9,1]8[ST]</a> ==1. This field is cleared when <a href="#">SATAx1[9,1]8[ST]</a> is written from 1 to 0 by software. This field is not cleared by a COMRESET or a software reset. |

**SATAx1[B,3]8 Port 1,0 Command Issue (PxCI)**

| Bits | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
|------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31:0 | <b>CI: Commands Issued.</b> Read; write-1-only; cleared-by-hardware. Reset: 0. This field is bit significant. Each bit corresponds to a command slot, where bit 0 corresponds to command slot 0. This field is set by software to indicate to the HBA that a command has been built in system memory for a command slot and may be sent to the device. When the HBA receives a FIS which clears the BSY, DRQ, and ERR bits for the command, it clears the corresponding bit in this register for that command slot. Bits in this field shall only be set to 1 by software when <a href="#">SATAx1[9,1]8[ST]</a> is set to 1. This field is also cleared when <a href="#">SATAx1[9,1]8[ST]</a> is written from 1 to 0 by software. |

**SATAx1[B,3]C Port 1,0 SNotification (PxSNTF)**

| Bits  | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
|-------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31:16 | Reserved.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| 15:0  | <b>PMN: PM Notify.</b> Read; write-1-to-clear. Reset: 0. This field is bit significant. Each bit corresponds to a Port Multiplier (PM) port number, where bit 0 corresponds to PM port 0 and bit 15 corresponds to PM port 15. This field indicates whether a particular device with the corresponding PM Port number issued a Set Device Bits FIS to the host with the Notification bit set. Individual bits are cleared by software writing 1 to the corresponding bit positions. This field is reset to default on a HBA Reset, but it is not reset by COMRESET or software reset. |

**SATAx1[C,4]0 Port 1,0 FIS-based Switching Control (PxFBS)**

| Bits  | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
|-------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31:20 | Reserved.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| 19:16 | <b>DWE: Device With Error.</b> Read-only; updated-by-hardware. Reset: 0. Set by hardware to the value of the Port Multiplier port number of the device that experienced a fatal error condition. This field is only valid when <a href="#">SATAx1[C,4]0[SDE]</a> ==1.                                                                                                                                                                                                                                                                                                                                            |
| 15:12 | <b>ADO: Active Device Optimization.</b> IF (D11F0x40[SubclassCodeWriteEnable] == 1) THEN Read-write. ELSE Read-only. ENDIF. Reset: 2h. This register exposes the number of active devices that the FIS-based switching implementation has been optimized for. When there are more devices active than indicated in this field, throughput of concurrent traffic may degrade. For optimal performance, software should limit the number of active devices based on this value. The minimum value for this field shall be 2h, indicating that at least two devices may be active with high performance maintained. |
| 11:8  | <b>DEV: Device To Issue.</b> Read-write. Reset: 0. Set by software to the Port Multiplier port value of the next command to issue. This field enables hardware to know the port the command is to be issued to without fetching the command header. Software shall not issue commands to multiple Port Multiplier ports on the same write of <a href="#">SATAx1[B,3]8</a> register.                                                                                                                                                                                                                              |
| 7:3   | Reserved.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |

|   |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
|---|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 2 | <b>SDE: Single Device Error.</b> Read-only. Reset: 0. 1=When a fatal error condition has occurred, hardware believes the error is localized to one device such that software's first error recovery step should be to utilize the <a href="#">SATAx1[C,4]0[DEC]</a> functionality. 0=When a fatal error condition has occurred, the error applies to the entire port and to clear the error <a href="#">SATAx1[9,1]8[ST]</a> shall be cleared to 0 by software. This bit is cleared on <a href="#">SATAx1[C,4]0[DEC]</a> being set to 1 or on <a href="#">SATAx1[9,1]8[ST]</a> being cleared to 0.   |
| 1 | <b>DEC: Device Error Clear.</b> Read; write-1-only; cleared-by-hardware. Reset: 0. When set to 1 by software, the HBA shall clear the device-specific error condition and the HBA shall flush any commands outstanding for the device that experienced the error, including clearing <a href="#">SATAx1[B,3]8</a> and <a href="#">SATAx1[B,3]4</a> bits for that device to 0. When hardware has completed error recovery actions, hardware shall clear the bit to 0. Software shall only set this bit to 1 if (( <a href="#">SATAx1[C,4]0[EN]</a> ==1) && ( <a href="#">SATAx1[C,4]0[SDE]</a> ==1)). |
| 0 | <b>EN: Enable.</b> Read-write. Reset: 0. 1=A Port Multiplier is attached and the HBA shall use FIS-based switching to communicate with it. 0=FIS-based switching is not being used. Software shall only change the value of this bit when <a href="#">SATAx1[9,1]8[ST]</a> ==0.                                                                                                                                                                                                                                                                                                                      |

### SATAx1[C,4]4 Port 1,0 Device Sleep (PxDEVSLP)

| Bits  | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |       |                 |      |            |    |            |       |                 |    |            |    |             |

Reset: 0. 0=The HBA does not enter DevSleep unless software directed via SATAx1[9,1]8[ICC]. 1=The HBA shall assert the DEVSLP signal after the port has been idle (SATAx1[B,3]8==0 and SATAx1[B,3]4==0) for the amount of time specified by the SATAx1[C,4]4[DITO]; If (SATAx24[DESO]== 1), the HBA shall assert the DEVSLP signal after the port has been idle for the amount of time specified by SATAx1[C,4]4[DITO] and the interface is in Slumber state (SATAx1[A,2]8[IPM]==6h).<br>This bit shall only be set to 1 if SATAx1[C,4]4[DSP]==1. |

### 3.26.3.3.3 Enclosure Buffer Management Registers

The Enclosure Buffer Management registers range from (D11F0x24 [AHCI Base Address (BAR5)] + SATAx1C[OFST]\*4 + 00h) to (D11F0x24 [AHCI Base Address (BAR5)] + SATAx1C[OFST]\*4 + FFh) within the memory mapped space.

#### SATA\_EMx00 Message Header

| Bits  | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |      |            |    |     |    |        |    |       |    |                                  |       |           |

**SATA\_EMx0C Write SGPIO Register Request (III)**

| Bits  | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
|-------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 255:0 | <p><b>DataRegister[7:0]: Data Register [7:0].</b> Read-write. Reset: 0. This field contains 256 bits of data registers ranging from (D11F0x24 [AHCI Base Address (BAR5)] + SATAx1C[OFST] * 4 + 0Ch) to (D11F0x24 [AHCI Base Address (BAR5)] + SATAx1C[OFST] * 4 + 2Bh). Once <a href="#">SATA_EMx04[REG_TYPE]</a>, <a href="#">SATA_EMx04[REG_INDX]</a>, and <a href="#">SATA_EMx08[REG_CNT]</a> are specified, the values in this field will be written to the internal copy of SGPIO registers.</p> |

### 3.26.4 USB Controllers

#### 3.26.4.1 USB 1.1 (OHCI)

The OHCI controllers can be disabled by programming [PMxEF](#).

##### 3.26.4.1.1 Devices 16h, 13h, 12h Function 0 (OHCI) Configuration Registers

See [3.1 \[Register Descriptions and Mnemonics\]](#) for a description of the register naming convention. See [2.7 \[Configuration Space\]](#) for details about how to access this space.

##### D[16,13,12]F0x00 Device/Vendor ID

| Bits  | Description                                                                                                                           |
|-------|---------------------------------------------------------------------------------------------------------------------------------------|
| 31:16 | <b>DeviceID: device ID.</b> Value: 7807h. This 16-bit field is assigned by the device manufacturer and identifies the type of device. |
| 15:0  | <b>VendorID: vendor ID.</b> Value: 1022h.                                                                                             |

##### D[16,13,12]F0x04 Status/Command

| Bits  | Description                                                                                                                                                                                                   |
|-------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31    | <b>ParityErrorDetected: parity error detected.</b> Read; set-by-hardware; write-1-to-clear. Reset: 0. Set by the device when it detects a parity error. This is not affected by ParityErrorEn.                |
| 30    | <b>SignaledSystemError: signaled system error.</b> Read; set-by-hardware; write-1-to-clear. Reset: 0. Set when the device asserts SERR#.                                                                      |
| 29    | <b>ReceivedMasterAbort: received master abort.</b> Read; set-by-hardware; write-1-to-clear. Reset: 0. Set by a master device when its transaction (except for Special Cycle) is terminated with master-abort. |
| 28    | <b>ReceivedTargetAbort: received target abort.</b> Read; set-by-hardware; write-1-to-clear. Reset: 0. Set by a master device when its transaction is terminated with target-abort.                            |
| 27    | <b>SignaledTargetAbort: signaled target abort.</b> Read; set-by-hardware; write-1-to-clear. Reset: 0. Set by a target device when it terminates a transaction with target-abort.                              |

| 10          | <b>RWE: remote wakeup enable.</b> Read-write. Reset: 0. This bit is used by <b>HCD</b> to enable or disable the remote wakeup feature upon the detection of upstream resume signaling. 1=If ( <b>OHCI[3:1]x0C[RD]==1</b> ), a remote wakeup is signaled to the host system. Setting this bit has no impact on the generation of hardware interrupt.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |             |                   |             |                   |     |          |     |                |     |           |     |            |
| 9           | <b>RWC: remote wakeup connected.</b> Read-write. Reset: 0. This bit indicates whether HC supports remote wakeup signaling. If remote wakeup is supported and used by the system it is the responsibility of system firmware to set this bit during POST. HC clears the bit upon a hardware reset but does not alter it upon a software reset. Remote wakeup signaling of the host system is host-bus-specific and is not described in this specification.                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |             |                   |             |                   |     |          |     |                |     |           |     |            |
| 8           | <b>IR: interrupt routing.</b> Read-write. Reset: 0. Specifies the routing of interrupts generated by events registered in <b>OHCI[3:1]x0C</b> . 0=All interrupts are routed to the normal host bus interrupt mechanism. 1=Interrupts are routed to the System Management Interrupt. <b>HCD</b> clears this bit upon a hardware reset, but it does not alter this bit upon a software reset. <b>HCD</b> uses this bit as a tag to indicate the ownership of HC.                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |             |                   |             |                   |     |          |     |                |     |           |     |            |
| 7:6         | <b>HCFS: host controller functional state.</b> Read-write. Reset: 0. <table><tr><td><u>Bits</u></td><td><u>Definition</u></td><td><u>Bits</u></td><td><u>Definition</u></td></tr><tr><td>00b</td><td>USBRESET</td><td>10b</td><td>USBOPERATIONAL</td></tr><tr><td>01b</td><td>USBRESUME</td><td>11b</td><td>USBSUSPEND</td></tr></table> A transition to USBOPERATIONAL from another state causes SOF generation to begin 1 ms later. <b>HCD</b> may determine whether HC has begun sending SOFs by reading <b>OHCI[3:1]x0C[SF]</b> . This field may be changed by HC only when in the USBSUSPEND state. HC may move from the USBSUSPEND state to the USBRESUME state after detecting the resume signaling from a downstream port. HC enters USBSUSPEND after a software reset, whereas it enters USBRESET after a hardware reset. The latter also resets the Root Hub and asserts subsequent reset signaling to downstream ports. | <u>Bits</u> | <u>Definition</u> | <u>Bits</u> | <u>Definition</u> | 00b | USBRESET | 10b | USBOPERATIONAL | 01b | USBRESUME | 11b | USBSUSPEND |
| <u>Bits</u> | <u>Definition</u>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  | <u>Bits</u> | <u>Definition</u> |             |                   |     |          |     |                |     |           |     |            |
| 00b         | USBRESET                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           | 10b         | USBOPERATIONAL    |             |                   |     |          |     |                |     |           |     |            |
| 01b         | USBRESUME                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          | 11b         | USBSUSPEND        |             |                   |     |          |     |                |     |           |     |            |
| 5           | <b>BLE: bulk list enable.</b> Read-write. Reset: 0. 1=Enable the processing of the Bulk list in the next frame. If cleared by <b>HCD</b> , processing of the Bulk list does not occur after the next SOF. HC checks this bit whenever it determines to process the list. When disabled, <b>HCD</b> may modify the list. If <b>OHCI[3:1]x2C [HC BulkCurrent ED]</b> is pointing to an ED to be removed, <b>HCD</b> must advance the pointer by updating <b>OHCI[3:1]x2C [HC BulkCurrent ED]</b> before re-enabling processing of the list.                                                                                                                                                                                                                                                                                                                                                                                          |             |                   |             |                   |     |          |     |                |     |           |     |            |

|             |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |             |                      |             |                      |     |     |     |     |     |     |     |     |

| 17:16 | <b>SOC: SchedulingOverrunCount.</b> Read-write. Reset: 0. These bits increment on each scheduling overrun error. It is initialized to 00b and wraps around at 11b. Increments when a scheduling overrun is detected even if <b>OHCI[3:1]x0C[SO]</b> has already been set. This is used by <b>HCD</b> to monitor any persistent scheduling problems.                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| 15:4  | Reserved.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| 3     | <b>OCR: OwnershipChange.</b> Read-write. Reset: 0. When set, HC will set the <b>OHCI[3:1]x0C[OC]</b> . This bit is set by an OS <b>HCD</b> to request a change of control of the HC. After the changeover, this bit is cleared and remains so until the next request from OS <b>HCD</b> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| 2     | <b>BLF: BulkListFilled.</b> Read-write. Reset: 0. This bit is used to indicate whether there are any TDs on the Bulk list. It is set by <b>HCD</b> whenever it adds a TD to an ED in the Bulk list. When HC begins to process the head of the Bulk list, it checks BLF. As long as ( <b>OHCI[3:1]x08[BLF]</b> ==0), HC will not start processing the Bulk list. If ( <b>OHCI[3:1]x08[BLF]</b> ==1), HC will start processing the Bulk list and will set BLF to 0. If HC finds a TD on the list, then HC will set <b>OHCI[3:1]x08[BLF]</b> =1, causing the Bulk list processing to continue. If no TD is found on the Bulk list, and if <b>HCD</b> does not set BulkList-Filled, then BulkListFilled will still be 0 when HC completes processing the Bulk list and Bulk list processing will stop. |

|   |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
|---|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 1 | <b>CLF: ControlListFilled.</b> Read-write. Reset: 0. This bit is used to indicate whether there are any TDs on the Control list. It is set by <b>HCD</b> whenever it adds a TD to an ED in the Control list. When HC begins to process the head of the Control list, it checks CLF. As long as ( <b>OHCI[3:1]x08[CLF]==0</b> ), HC will not start processing the Control list. If ( <b>OHCI[3:1]x08[CLF]==1</b> ) the HC starts processing the Control list and will set ControlListFilled to 0. If HC finds a TD on the list, then HC will set <b>OHCI[3:1]x08[CLF]=1</b> , causing control list processing to continue. If no TD is found on the Control list, and if the <b>HCD</b> does not set <b>OHCI[3:1]x08[CLF]=1</b> , then <b>OHCI[3:1]x08[CLF]</b> will still be 0 when HC completes processing the Control list and Control list processing will stop. |
| 0 | <b>HCR: HostControllerReset.</b> Read; write-1-only; cleared-when-done. Reset: 0. This bit is set by <b>HCD</b> to initiate a software reset of HC. Regardless of the functional state of HC, it moves to the USB-SUSPEND state in which most of the operational registers are reset except those stated otherwise; e.g., <b>OHCI[3:1]x04[IR]</b> , and no Host bus accesses are allowed. The reset operation must be completed within 10 ms. This bit, when set, should not cause a reset to the Root Hub, and no subsequent reset signaling should be asserted to its downstream ports.                                                                                                                                                                                                                                                                           |

### OHCI[3:1]x0C HC Interrupt Status

| Bits | Description                                                                                                                                                                                                                                                                                                 |
|------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31   | Reserved.                                                                                                                                                                                                                                                                                                   |
| 30   | <b>OC: OwnershipChange.</b> Read-write. Reset: 0. 1= The HC detected that the <b>HCD</b> set <b>OHCI[3:1]x08[OCR]</b> . This event, when unmasked, will always generate a System Management Interrupt (SMI) immediately. This bit is tied to 0b when the SMI pin is not implemented.                        |
| 29:7 | Reserved.                                                                                                                                                                                                                                                                                                   |
| 6    | <b>RHSC: RootHubStatusChange.</b> Read-write. Reset: 0. This bit is set when the content of <b>OHCI[3:1]x50</b> or the content of any of <b>OHCI[3:1]x[60:54:step4]</b> has changed.                                                                                                                        |
| 5    | <b>FNO: FrameNumberOverflow.</b> Read-write. Reset: 0. This bit is set when the FrameNumber MSB <b>OHCI[3:1]x3C[FN[15]]</b> changes value from 0 to 1 or from 1 to 0 and after FrameNumber has been updated.                                                                                                |
| 4    | <b>UE: UnrecoverableError.</b> Read-write. Reset: 0. 1=The HC detected a system error not related to USB. HC should not proceed with any processing or signaling before the system error has been corrected. <b>HCD</b> clears this bit after HC has been reset.                                            |
| 3    | <b>RD: ResumeDetected.</b> Read-write. Reset: 0. 1=The HC detected that a device on the USB is asserting resume signaling. It is the transition from no resume signaling to resume signaling causing this bit to be set. This bit is not set when <b>HCD</b> sets the USBRESUME state.                      |
| 2    | <b>SF: StartOfFrame.</b> Read-write. Reset: 0. This bit is set by HC at each start of a frame and after the update of HccaFrameNumber. HC also generates a SOF token at the same time.                                                                                                                      |
| 1    | <b>WDH: WritebackDoneHead.</b> Read-write. Reset: 0. This bit is set immediately after HC has written HcDoneHead to HccaDoneHead. Further updates of the HccaDoneHead will not occur until this bit has been cleared. <b>HCD</b> should only clear this bit after it has saved the content of HccaDoneHead. |
| 0    | <b>SO: SchedulingOverrun.</b> Read-write. Reset: 0. This bit is set when the USB schedule for the current Frame overruns and after the update of HccaFrameNumber. A scheduling overrun will also cause the SchedulingOverrunCount of HcCommandStatus to be incremented.                                     |

**OHCI[3:1]x10 HC Interrupt Enable**

| Bits | Description                                                                                                                                                                                                                                                                                        |
|------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31   | <b>MIE: MasterInterruptEnable.</b> Read; write-1-only. Reset: 0. 1=Enables interrupt generation due to events specified in the other bits of this register. See corresponding field in <a href="#">OHCI[3:1]x14</a> for disable. This is used by <a href="#">HCD</a> as a Master Interrupt Enable. |
| 30   | <b>OC: OwnershipChange.</b> Read; write-1-only. Reset: 0. 1=Enable interrupt generation due to Ownership Change. See corresponding field in <a href="#">OHCI[3:1]x14</a> for disable.                                                                                                              |
| 29:7 | Reserved.                                                                                                                                                                                                                                                                                          |
| 6    | <b>RHSC: RootHubStatusChange.</b> Read; write-1-only. Reset: 0. 1=Enable interrupt generation due to Root Hub Status Change. See corresponding field in <a href="#">OHCI[3:1]x14</a> for disable.                                                                                                  |
| 5    | <b>FNO: FrameNumberOverflow.</b> Read; write-1-only. Reset: 0. 1=Enable interrupt generation due to Frame Number Overflow. See corresponding field in <a href="#">OHCI[3:1]x14</a> for disable.                                                                                                    |
| 4    | <b>UE: UnrecoverableError.</b> Read; write-1-only. Reset: 0. 1=Enable interrupt generation due to Unrecoverable Error. See corresponding field in <a href="#">OHCI[3:1]x14</a> for disable.                                                                                                        |
| 3    | <b>RD: ResumeDetect.</b> Read; write-1-only. Reset: 0. 1=Enable interrupt generation due to Resume Detect. See corresponding field in <a href="#">OHCI[3:1]x14</a> for disable.                                                                                                                    |
| 2    | <b>SF: StartofFrame.</b> Read; write-1-only. Reset: 0. 1=Enable interrupt generation due to Start of Frame. See corresponding field in <a href="#">OHCI[3:1]x14</a> for disable.                                                                                                                   |
| 1    | <b>WDH: HcDoneHeadWriteback.</b> Read; write-1-only. Reset: 0. 1=Enable interrupt generation due to HcDoneHead Writeback. See corresponding field in <a href="#">OHCI[3:1]x14</a> for disable.                                                                                                     |
| 0    | <b>SO: SchedulingOverrun.</b> Read; write-1-only. Reset: 0. 1=Enable interrupt generation due to Scheduling Overrun. See corresponding field in <a href="#">OHCI[3:1]x14</a> for disable.                                                                                                          |

**OHCI[3:1]x14 HC Interrupt Disable**

Reset: 8000\_0000h.

| Bits | Description                                                                                                                                                                                                            |

### OHCI[3:1]x30 HC Done Head

| Bits | Description                                                                                                                                                                                                                                                                                                                       |
|------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31:4 | <b>DH: DoneHead.</b> Read-write. Reset: 0. When a TD is completed, HC writes the content of HcDoneHead to the NextTD field of the TD. HC then overwrites the content of HcDoneHead with the address of this TD. This is set to 0 whenever HC writes the content of this register to HCCA. It also sets <b>OHCI[3:1]x0C[WDH]</b> . |
| 3:0  | Reserved.                                                                                                                                                                                                                                                                                                                         |

### OHCI[3:1]x34 HC Frame Interval

| Bits  | Description                                                                                                                                                                                                                                                                                                                                                                                                                   |
|-------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31    | <b>FIT: frame interval toggle.</b> Read-write. Reset: 0. <b>HCD</b> toggles this bit whenever it loads a new value to <b>OHCI[3:1]x34[FI]</b> .                                                                                                                                                                                                                                                                               |
| 30:16 | <b>FSMPS: FS largest data packet.</b> Read-write. Reset: 0. This field specifies a value which is loaded into the Largest Data Packet Counter at the beginning of each frame. The counter value represents the largest amount of data in bits which can be sent or received by the HC in a single transaction at any given time without causing scheduling overrun. The field value is calculated by the <b>HCD</b> .         |
| 15:14 | Reserved.                                                                                                                                                                                                                                                                                                                                                                                                                     |
| 13:0  | <b>FI: frame interval.</b> Read-write; updated-by-hardware. Reset: 2EDFh. This specifies the interval between two consecutive SOFs in bit times. <b>HCD</b> should store the current value of this field before resetting HC. Programming <b>OHCI[3:1]x08[HCR]=1</b> causes the HC to overwrite this field with the reset value. <b>HCD</b> may choose to restore the stored value upon the completion of the reset sequence. |

### OHCI[3:1]x38 HC Frame Remaining

| Bits | Description |
|------|-------------|
|------|-------------|

|       |                                                                                                                                                                                                                                                                                                                                                                                     |
|-------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31    | <b>FRT: FrameRemainingToggle.</b> Read-only. Reset: 0. This bit is loaded from the FrameIntervalToggle field of HcFmInterval whenever FrameRemaining reaches 0. This bit is used by <a href="#">HCD</a> for the synchronization between FrameInterval and FrameRemaining.                                                                                                           |
| 30:14 | Reserved.                                                                                                                                                                                                                                                                                                                                                                           |
| 13:0  | <b>FR: FrameRemaining.</b> Read-only. Reset: 0. This counter is decremented at each bit time. When it reaches 0, it is reset by loading the FrameInterval value specified in HcFmInterval at the next bit time boundary. When entering the USBOPERATIONAL state, HC re-loads the content with the FrameInterval field of HcFmInterval and uses the updated value from the next SOF. |

### OHCI[3:1]x3C HC Frame Number

| Bits  | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
|-------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31:16 | Reserved.                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| 15:0  | <b>FN[15:0]: FrameNumber.</b> Read-only. Reset: 0. This is incremented when HcFmRemaining is re-loaded. It will be rolled over to 0h after FFFFh. When entering the USBOPERATIONAL state, this will be incremented automatically. The content will be written to HCCA after HC has incremented FrameNumber at each frame boundary and sent a SOF but before HC reads the first ED in that Frame. After writing to HCCA, HC will set <a href="#">OHCI[3:1]x0C[SF]</a> . |

### OHCI[3:1]x40 HC Periodic Start

| Bits  | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
|-------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31:14 | Reserved.                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| 13:0  | <b>PS: PeriodicStart.</b> Read-write. Reset: 0. This bit is set by <a href="#">HCD</a> during the HC initialization. The value is calculated roughly as 10% off from HcFmInterval. A typical value will be 3E67h. When HcFmRemaining reaches the value specified, processing of the periodic lists will have priority over Control/Bulk processing. HC will therefore start processing the interrupt list after completing the current Control or Bulk transaction that is in progress. |

### OHCI[3:1]x44 HC LS Threshold

| Bits  | Description                                                                                                                                                                                                                                                                                                                                                               |
|-------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31:12 | Reserved.                                                                                                                                                                                                                                                                                                                                                                 |
| 11:0  | <b>LST: LSThreshold.</b> Read-write. Reset: 628h. This field contains a value which is compared to the FrameRemaining field prior to initiating a Low Speed transaction. The transaction is started only if FrameRemaining is equal or greater than this field. The value is calculated by <a href="#">HCD</a> with the consideration of transmission and setup overhead. |

| 31:24 | <b>POTPGT: PowerOnToPowerGoodTime.</b> Read-write. This field specifies the duration <b>HCD</b> has to wait before accessing a powered-on port of the Root Hub. It is implementation-specific. The unit of time is 2 ms. The duration is calculated as POTPGT * 2 ms.                                                                                                                                                                                                                                                                                                                                                                                         |
| 23:13 | Reserved.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| 12    | <b>NOCP: NoOverCurrentProtection.</b> Read-write. Specifies how the over-current status for the Root Hub ports is reported. When this bit is cleared, the OverCurrentProtectionMode field specifies global or per-port reporting. 0=Over-current status is reported collectively for all downstream ports. 1=No over-current protection supported.                                                                                                                                                                                                                                                                                                            |
| 11    | <b>OCPM: OverCurrentProtectionMode.</b> Read-write. Specifies how the over-current status for the Root Hub ports are reported. At reset, this field should reflect the same mode as PSM. This field is valid only if (OHCI[3:1]x48[NOCP]==0). 0=Over-current status is reported collectively for all downstream ports. 1=Over-current status is reported on a per-port basis.                                                                                                                                                                                                                                                                                 |
| 10    | <b>DT: DeviceType.</b> Value: 0. 0=Specifies that the Root Hub is not a compound device. The Root Hub is not permitted to be a compound device.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| 9     | <b>NPS: NoPowerSwitching.</b> Read-write. Reset: 1. Specifies whether power switching is supported or ports are always powered. It is implementation-specific. When this bit is cleared, the PSM specifies global or per-port switching. 0=Ports are power switched. 1=Ports are always powered on when the HC is powered on.                                                                                                                                                                                                                                                                                                                                 |
| 8     | <b>PSM: PowerSwitchingMode.</b> Read-write. Reset: 1. Specifies how the power switching of the Root Hub ports is controlled. It is implementation-specific. This field is only valid if the NoPowerSwitching field is cleared. 0=All ports are powered at the same time. 1=Each port is powered individually. This mode allows port power to be controlled by either the global switch or per-port switching. If the OHCI[3:1]x4C[PPCM] bit is set, the port responds only to port power commands (SetPortPower/ClearPortPower). If the port mask is cleared, then the port is controlled only by the global power switch (SetrGlobalPower/ClearGlobalPower). |
| 7:0   | <b>NDP: NumberDownstreamPorts.</b> Read-only. Specifies the number of downstream ports supported by the Root Hub. It is implementation-specific. The minimum number of ports is 1. The maximum number of ports supported by OpenHCI is 15. Note: For OHCI 1/OHCI 2 (device-13h:12h, func-0), each OHCI controller owns 4 downstream ports. OHCI 3 (device-16h, func-0) owns 2 downstream ports.                                                                                                                                                                                                                                                               |

| 31:9 | Reserved.                                                                                                                                                                                                                                                                                                |
| 8    | <b>A20State.</b> Read-write. Indicates current state of Gate A20 on keyboard controller. Used to compare against value written to 60h when GateA20Sequence is active.                                                                                                                                    |
| 7    | <b>IRQ12Active.</b> Read; write-1-to-clear. 1=A positive transition on IRQ12 from the keyboard controller has occurred.                                                                                                                                                                                  |
| 6    | <b>IRQ1Active.</b> Read; write-1-to-clear. 1=A positive transition on IRQ1 from the keyboard controller has occurred.                                                                                                                                                                                    |
| 5    | <b>GateA20Sequence.</b> Read-write. Set by HC when (IO port 64h==D1h). Cleared by HC on write to (IO port 64h!=D1h).                                                                                                                                                                                     |
| 4    | <b>ExternalIRQEn.</b> Read-write. 1=Enable IRQ1 and IRQ12 from the keyboard controller to cause an emulation interrupt. The function controlled by this bit is independent of the setting of the Emulation-Enable bit in this register.                                                                  |
| 3    | <b>IRQEn.</b> Read-write. 1=Enable the HC generation of IRQ1 or IRQ12 as long as the (OHCI[3:1]x10C[OutputFull] ==1). IF (OHCI[3:1]x10C[AuxOutputFull]==0) THEN IRQ1 is generated. ELSE IRQ12 is generated.                                                                                              |
| 2    | <b>CharacterPending.</b> Read-write. 1=An emulation interrupt is generated when the OutputFull bit of the HceStatus register is set to 0.                                                                                                                                                                |
| 1    | <b>EmulationInterrupt.</b> Read-only. This bit is a static decode of the emulation interrupt condition.                                                                                                                                                                                                  |
| 0    | <b>EmulationEnable.</b> Read-write. 1=Enable HC legacy keyboard and mouse emulation. The HC decodes accesses to IO registers 60h and 64h and generates IRQ1 and/or IRQ12 when appropriate. Additionally, the HC generate s an emulation interrupt at appropriate times to invoke the emulation software. |

### OHCI[3:1]x104 HCE Input

| Bits | Description                                                                                               |
|------|-----------------------------------------------------------------------------------------------------------|
| 31:8 | Reserved.                                                                                                 |
| 7:0  | <b>InputData.</b> Read-write. Reset: 0. This register holds data that is written to IO ports 60h and 64h. |

### OHCI[3:1]x108 HCE Output

| Bits | Description                                                                                                                                          |
|------|------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31:8 | Reserved.                                                                                                                                            |
| 7:0  | <b>OutputData.</b> Read-write. Reset: 0. This register hosts data that is returned when an IO read of port 60h is performed by application software. |

**OHCI[3:1]x10C HCE Status**

Reset: 0000\_0000h.

| Bits | Description                                                                                                                                                                                                                                                                                                                                                                                                          |
|------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31:8 | Reserved.                                                                                                                                                                                                                                                                                                                                                                                                            |
| 7    | <b>Parity.</b> Read-write. 1=Indicates parity error on keyboard/mouse data.                                                                                                                                                                                                                                                                                                                                          |
| 6    | <b>TimeOut.</b> Read-write. 1=Indicates a timeout.                                                                                                                                                                                                                                                                                                                                                                   |
| 5    | <b>AuxOutputFull.</b> Read-write. IRQ12 is asserted whenever this bit is set to 1 and OutputFull is set to 1 and the IRQEn bit is set.                                                                                                                                                                                                                                                                               |
| 4    | <b>InhibitSwitch.</b> Read-write. This bit reflects the state of the keyboard inhibit switch and is set if the keyboard is NOT inhibited.                                                                                                                                                                                                                                                                            |
| 3    | <b>CmdData.</b> Read-write. The HC sets this bit to 0 on an IO write to port 60h and to 1 on an IO write to port 64h.                                                                                                                                                                                                                                                                                                |
| 2    | <b>Flag.</b> Read-write. Nominally used as a system flag by software to indicate a warm or cold boot.                                                                                                                                                                                                                                                                                                                |
| 1    | <b>InputFull.</b> Read-write. Except for the case of a Gate A20 sequence, this bit is set to 1 on an IO write to address 60h or 64h. While this bit is set to 1 and emulation is enabled, an emulation interrupt condition exists.                                                                                                                                                                                   |
| 0    | <b>OutputFull.</b> Read-write. The HC sets this bit to 0 on a read of IO port 60h. If IRQEn is set and AuxOutputFull is set to 0, then an IRQ1 is generated as long as this bit is set to 1. If IRQEn is set and AuxOutputFull is set to 1, then an IRQ12 is generated as long as this bit is set to 1. While this bit is 0 and CharacterPending in HceControl is set to 1, an emulation interrupt condition exists. |

**3.26.4.2 USB 2.0 (EHCI)**

The EHCI controllers can be disabled by programming **PMxEF**.

**3.26.4.2.1 Devices 16h, 13h, 12h Function 2 (EHCI) Configuration Registers**

See 3.1 [Register Descriptions and Mnemonics] for a description of the register naming convention. See 2.7 [Configuration Space] for details about how to access this space.

| 31:24 | Reserved.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| 23:20 | <b>DebugPortNumber.</b> Read-only. Reset: 1. This register identifies which of the host controller ports is the debug port. The value is the port number (one-based) of the debug port. A non-zero value in this field indicates the presence of a debug port. The value in this register must not be greater than <a href="#">EHCI[3:1]x04[NPorts]</a> . Writing <a href="#">EHCI[3:1]xA0[DebugPortNumberReMapping]</a> updates this field.                                                                                                                                                                                                                                                                      |
| 19:17 | Reserved.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| 16    | <b>PortIndicators.</b> Read-only. Indicates whether the ports support port indicator control. 1=The port status and control registers include a read/writable field for controlling the state of the port indicator.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| 15:12 | <b>N_CC: number of companion controllers.</b> Read-only. Indicates the number of companion controllers associated with this USB 2.0 host controller. 0=Indicates there are no companion host controllers. Port-ownership hand-off is not supported. Only high-speed devices are supported on the host controller root ports. A value larger than 0 in this field indicates there are companion USB 1.1 host controller(s). Port-ownership handoffs are supported. High-speed, Full-speed and Low-speed devices are supported on the host controller root ports.                                                                                                                                                   |
| 11:8  | <b>N_PCC: NumberOfPortsPerCompanionController.</b> Read-only. Indicates the number of ports supported per companion host controller. It is used to indicate the port routing configuration to system software. For example, if NPorts has a value of 6 and N_CC has a value of 2, then N_PCC could have a value of 3. The convention is that the first N_PCC ports are assumed to be routed to companion controller 1, the next N_PCC ports to companion controller 2, etc. In the previous example, the N_PCC could have been 4, where the first 4 are routed to companion controller 1 and the last two are routed to companion controller 2. The number in this field must be consistent with NPorts and N_CC. |

|             |                                                                                                                                                                                                                                                                                                                                                                                                           |             |                   |    |           |       |                |
|-------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------|-------------------|----|-----------|-------|----------------|
| 7           | <b>PortRoutingRules.</b> Read-only. Specifies how all ports are mapped to companion controllers. 0=The first N_PCC ports are routed to the lowest numbered function companion host controller, the next N_PCC port are routed to the next lowest function companion controller, and so on. 1=The port routing is explicitly enumerated by the first N_PORTS elements of the HCSP-PORTROUTE array.         |             |                   |    |           |       |                |
| 6:5         | Reserved.                                                                                                                                                                                                                                                                                                                                                                                                 |             |                   |    |           |       |                |
| 4           | <b>PPC: PortPowerControl.</b> Read-only. Specifies whether the host controller implementation includes port power control. 1=The ports have port power switches. 0=The port does not have port power switches. The value of this field affects the functionality of <a href="#">EHCI[3:1]x[70,6C,68,64][PortPower]</a> .                                                                                  |             |                   |    |           |       |                |
| 3:0         | <b>NPorts.</b> Read-only. Specifies the number of physical downstream ports implemented on this host controller. The value of this field determines how many port registers are addressable in the Operational Register Space.<br><table> <tr> <td><u>Bits</u></td><td><u>Definition</u></td></tr> <tr> <td>0h</td><td>undefined</td></tr> <tr> <td>Fh-1h</td><td>&lt;NPorts&gt; Ports</td></tr> </table> | <u>Bits</u> | <u>Definition</u> | 0h | undefined | Fh-1h | <NPorts> Ports |
| <u>Bits</u> | <u>Definition</u>                                                                                                                                                                                                                                                                                                                                                                                         |             |                   |    |           |       |                |
| 0h          | undefined                                                                                                                                                                                                                                                                                                                                                                                                 |             |                   |    |           |       |                |

This field is used by system software to specify the minimum amount of time the host controller will drive the K-state during a host-initiated resume from a LPM state (e.g. L1), and is conveyed to each LPM-enabled device (via the HIRD bits within an LPM Token’s bmAttributes field) upon entry into a low-power state.<br><table><tr><th>Bits</th><th>Definition</th></tr><tr><td>Fh-0h</td><td>(&lt;HostInitiatedResumeDuration&gt; *75 us) + 50 us</td></tr></table>                                                                                                                                                                                                                      | Bits | Definition                     | Fh-0h | (<HostInitiatedResumeDuration> *75 us) + 50 us |     |          |     |                                |     |               |     |                        |     |                |     |                        |     |                |     |                        |

| 6           | <b>InterruptOnAsyncAdvanceDoorbell: Interrupt on Async Advance Doorbell.</b> Read; cleared-by-hardware; write-1-only. Reset: 0. This bit is used as a doorbell by software to tell the host controller to issue an interrupt the next time it advances asynchronous schedule. Software must write a 1 to this bit to ring the doorbell. When the host controller has evicted all appropriate cached schedule state, it sets <a href="#">EHCI[3:1]x24[InterruptOnAsyncAdvance]</a> to 1 and clears this bit to 0.<br>Software should not write a 1 to this bit when the asynchronous schedule is disabled. Doing so will yield undefined results.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |             |                                   |             |                   |     |                          |     |                         |     |                         |     |                                   |
| 5           | <b>AsynchronousScheduleEnable: Asynchronous Schedule Enable.</b> Read-write. Reset: 0. This bit controls whether the host controller skips processing the Asynchronous Schedule. 0=Do not process the Asynchronous Schedule. 1=Use <a href="#">EHCI[3:1]x38</a> to access Asynchronous Schedule.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |             |                                   |             |                   |     |                          |     |                         |     |                         |     |                                   |
| 4           | <b>PeriodicScheduleEnable: Periodic Schedule Enable.</b> Read-write. Reset: 0. This bit controls whether the host controller skips processing the Periodic Schedule. 0=Do not process the Periodic Schedule. 1=Use <a href="#">EHCI[3:1]x34</a> to access the Periodic Schedule.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |             |                                   |             |                   |     |                          |     |                         |     |                         |     |                                   |
| 3:2         | <b>FrameListSize: frame list size.</b> IF (( <a href="#">EHCI[3:1]x08[ProgrammableFrameListFlag]</a> ==1)    ( <a href="#">EHCI[3:1]x08[Frame32PeriodicListCapability]</a> ==1)) THEN Read-write. | 1           | <b>HCRESET: Host Controller Reset.</b> Read; cleared-by-hardware; write-1-only. Reset: 0. This control bit is used by software to reset the host controller. The effects of this on Root Hub registers are similar to a Chip Hardware Reset. Software must reinitialize the host controller in order to return the host controller to an operational state.<br>1=The Host Controller resets its internal pipelines, timers, counters, state machines, etc. to their initial value; Any transaction currently in progress on USB is immediately terminated; A USB reset is not driven on downstream ports; PCI Configuration registers are not affected by this reset; All operational registers, including port registers and port state machines are set to their initial values; Port ownership reverts to the companion host controller(s).<br>Software should not set this bit to a 1 when <a href="#">EHCI[3:1]x24[HCHalted]</a> ==0. Attempting to reset an actively running host controller will result in undefined behavior.                                                                                                 |             |                                   |             |                   |     |                          |     |                         |     |                         |     |                                   |
| 0           | <b>RunStop: Run/Stop.</b> Read-write. Reset: 0. 1=Run; the Host Controller proceeds with execution of the schedule as long as this bit is set to 1. 0=Stop; the Host Controller completes the current and any actively pipelined transactions on the USB and then halts within 16 micro-frames after software clears this bit.<br>Software must not write a 1 to this field unless <a href="#">EHCI[3:1]x24[HCHalted]</a> ==1. Doing so will yield undefined results.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |             |                                   |             |                   |     |                          |     |                         |     |                         |     |                                   |

Reset: 0. 1=Indicate the assertion of interrupt source caused by EHCI[3:1]x20[InterruptOnAsyncAdvanceDoorbell].</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |     |            |     |        |     |        |     |     |      |         |
| 4     | <p><b>HostSystemError: Host System Error.</b> Read; set-by-hardware; write-1-to-clear. Reset: 0. 1=A serious error occurs during a host system access involving the host controller module. In a PCI system, conditions that set this bit to 1 include PCI Parity error, PCI Master Abort, and PCI Target Abort. When this error occurs, the host controller clears EHCI[3:1]x20[RunStop] to prevent further execution of the scheduled TDs.</p>                                                                                                                                                                                                                                                                                                                                                                             |     |            |     |        |     |        |     |     |      |         |
| 3     | <p><b>FrameListRollover: Frame List Rollover.</b> Read; set-by-hardware; write-1-to-clear. Reset: 0. 1=EHCI[3:1]x2C[FrameIndex] rolls over from its maximum value to zero. The exact Frame List Index value at which the rollover occurs depends on the frame list size. For example, if the frame list size as programmed by EHCI[3:1]x20[FrameListSize] is 1024, then a frame list rollover would occur every time EHCI[3:1]x2C[FrameIndex[13]] toggles. Similarly, a frame list rollover would occur every time EHCI[3:1]x2C[FrameIndex[12]] toggles for a 512 frame list. Note this behavior is different for a 32 frame list where a rollover event occurs every time EHCI[3:1]x2C[FrameIndex[13]] toggles (same as 1024).</p>                                                                                          |     |            |     |        |     |        |     |     |      |         |

|   |                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |

| 13:0  | <p><b>FrameIndex: Frame Index.</b> Read-write; updated-by-hardware. Reset: 0. This register is used by the host controller to index into the periodic frame list. The register updates every 125 microseconds (once each micro-frame). Bits [N:3] are used to select a particular entry in the Periodic Frame List during periodic schedule execution. The number of bits used for the index depends on <a href="#">EHCI[3:1]x20[FrameListSize]</a>.</p> <p>This register must be written as a DWord. Byte writes produce undefined results. This register cannot be written unless <a href="#">EHCI[3:1]x24[HCHalted]</a>==1. Writes to this register also affect the SOF value. The host controller behaves slightly different when using a 32-frame Frame List Size, specifically it continues to count FrameIndex up to a full 1024 frames, transmit SOF values from 0 to 2047, and generate Frame List Rollover events (when enabled) every 1024 frames - exactly as if a 1024 frame list size was employed. The host controller will only reference 32 elements on the periodic schedule, however. This is accomplished by formulating the Periodic Frame List Element Address using {FrameIndex[N:3] modulo 32} rather than FrameIndex[N:3]. The same mapping should be done by system software whenever it needs to correlate the current FrameIndex value to a specific periodic schedule element. Note this new behavior only applies to a 32-frame list.</p> |

**EHCI[3:1]x30 Control Data Structure Segment**

| Bits | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
|------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31:0 | <p><b>CtrlDSSegment.</b> IF (<a href="#">EHCI[3:1]x08[AddressingCapability64Bit]</a>==0) THEN RAZ. ELSE Read-write. ENDIF. Reset: 0. Specifies the most significant address bits [63:32] for all EHCI data structures if <a href="#">EHCI[3:1]x08[AddressingCapability64Bit]</a>==1. This register is concatenated with the link pointer from either <a href="#">EHCI[3:1]x34</a>, or <a href="#">EHCI[3:1]x38</a>, or any control data structure link field to construct a 64-bit address.</p> |

**EHCI[3:1]x34 Periodic Frame List Base Address**

| Bits  | Description                                                                                                                                                                                                                                                                                                                            |
|-------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31:12 | <p><b>BaseAddress: Base Address.</b> Read-write. Reset: 0. Specifies the beginning address [31:12] of the Periodic Frame List in the system memory. If (<a href="#">EHCI[3:1]x08[AddressingCapability64Bit]</a>==1), the most significant 32 bits of every control data structure address comes from <a href="#">EHCI[3:1]x30</a>.</p> |
| 11:0  | Reserved. Must be written as 0s. During runtime, the values of these bits are undefined.                                                                                                                                                                                                                                               |

| 0    | <b>CF: Configure Flag.</b> Read-write. Reset: 0. This bit controls the default port-routing control logic. Software sets this bit as the last action in its process of configuring the host controller. 0=Port routing control logic default-routes each port to an implementation dependent classic host controller. 1=Port routing control logic default-routes all ports to this host controller. |

| 9     | <b>SuspendUsingL1: Suspend using L1.</b> Read-write. Reset: 0. 0=The host controller will employ the legacy (L2) suspend mechanism. 1=If a non-zero value is specified in DeviceAddress, the host controller will generate an LPM Token to enter the L1 state whenever software writes a 1 to the Suspend bit, as well as L1 exit timing during any device- or host-initiated resume. Software should only set this bit when the device attached immediately downstream of this root port supports L1 transitions.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |      |            |     |                                               |     |                                                      |     |                                                   |     |                                                      |
| 8     | <p><b>PortReset: Port Reset.</b> Read-write. Reset: 0. 1=Port is in Reset. 0=Port is not in Reset. Software writes 1 to start the bus reset sequence; It must keep this bit at a 1 long enough to ensure the reset sequence completes. Software writes 0 to terminate the bus reset sequence; This bit will not read as a 0 until after the reset has completed.</p> <p>When software writes this bit to a 1, it must also write a 0 to the PortEnable bit. If the port is in high-speed mode after reset is complete, the host controller will automatically enable this port (e.g. set the Port Enable bit to a 1). <code>EHCI[3:1]x24[HCHalted]</code> should be a 0 before software attempts to use this bit. The host controller may hold Port Reset asserted to a 1 when the HCHalted bit is a 1. This field is 0 if <code>PortPower==0</code>.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |      |            |     |                                               |     |                                                      |     |                                                   |     |                                                      |
| 7     | <p><b>Suspend.</b> Read; cleared-by-hardware; write-1-only. Reset: 0. 0=IF (<code>EHCI[3:1]x[70,6C,68,64][PortEnable] == 1</code>) THEN Port is enabled. ELSE Port is disabled. ENDIF. 1=IF (<code>EHCI[3:1]x[70,6C,68,64][PortEnable] == 1</code>) THEN Port is in suspend state; The port can be in either L1 or L2 suspend state depending on SuspendUsingL1. ELSE Port is disabled. ENDIF.</p> <p>When in suspend state, downstream propagation of data is blocked on this port, except for port reset. If this bit is written with a 1 when a transaction is in progress then the blocking will not occur until the end of the current transaction. In the suspend state, the port is sensitive to resume detection. Additional status for L1-based transitions is provided to software via the SuspendStatus field. This field is 0 if <code>PortPower==0</code>. If system software sets this bit to a 1 when the port is not enabled (i.e. <code>PortEnable == 0</code>) the results are undefined. A write of 0 to this bit is ignored by the host controller. The host controller will unconditionally set this bit to a 0 when:</p> <ul style="list-style-type: none"> <li>• Software sets the ForcePortResume bit to a 0 from a 1.</li> <li>• Software sets the PortReset bit to a 1 from a 0.</li> <li>• Whenever PortPower is zero.</li> </ul> |      |            |     |                                               |     |                                                      |     |                                                   |     |                                                      |

| 6 | <p><b>ForcePortResume: Force Port Resume.</b> Read-write; set-by-hardware. Reset: 0. 1=Resume detected/driven on port. 0=No resume (K-state) detected/driven on port. This field is 0 if PortPower==0.</p> <p>This functionality defined for manipulating this bit depends on the value of the Suspend and SuspendUsingL1 bits. For example, if the port is not suspended (Suspend and Enabled bits are a 1) and software transitions this bit to a 1, then the effects on the bus are undefined.</p> <p>The Host Controller sets this bit to a 1 if a J-to-K transition is detected while the port is in the Suspend state. In this case, EHCI[3:1]x24[PortChangeDetect] and/or EHCI[3:1]x24[PortNChangeDetect] will also be set to 1.</p> <p>Software sets this bit to a 1 to drive resume signaling. If software sets this bit to a 1, the host controller must not set EHCI[3:1]x24[PortChangeDetect] and/or EHCI[3:1]x24[PortNChangeDetect]. Writing a 0 (from 1) causes the port to return to high-speed mode. This bit will remain a 1 until the port has switched to the high-speed idle. The host controller must complete this transition within 2 milliseconds of software setting this bit to a 0.</p> <p>For legacy (L2) transitions, software must appropriately time the Resume and set this bit to a 0 when the appropriate amount of time has elapsed. Software does not need to time resume signaling for L1 transactions as host controller hardware will automatically enforce the necessary timing and clear this bit when the port has fully resumed. Software can influence the amount of time hardware will drive resume signaling during L1 exit via EHCI[3:1]x20[HostInitiatedResumeDuration].</p> |

| 3:0  | <b>UsbBatteryChargerEnable.</b> Read-write. Reset: 0. One bit controls one respective port. For each bit, 1=Enable USB PHY battery charger function for the port. |

### 3.26.4.3 USB 3.0 (xHCI)

The xHCI controller has a PCI configuration register space and two memory mapped IO register spaces. The PCI configuration register space uses device 10h function 0 and is defined below as D10F0xXX. The two memory mapped IO register spaces are defined in 3.27.4.3.2 [xHCI Memory Mapped IO Configuration Registers] and 3.26.4.3.2 [xHCI Power Management Registers].

#### 3.26.4.3.1 Device 10h Function 0 (xHCI) Configuration Registers

See 3.1 [Register Descriptions and Mnemonics] for a description of the register naming convention. See 2.7 [Configuration Space] for details about how to access this space.

##### D10F0x00 Device/Vendor ID

| Bits  | Description                                                                                                                                                   |
|-------|---------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31:16 | <b>DeviceID: Device ID.</b> Read-only. Reset: 7814h. Device Identifier. Programmable through PCI/JTAG path and locked by (D10F0x4C_x04[CfgWriteOnceLock]==1). |
| 15:0  | <b>VendorID: Vendor ID.</b> Read-only. Reset: 1022h. Vendor Identifier. Programmable through PCI/JTAG path and locked by (D10F0x4C_x04[CfgWriteOnceLock]==1). |

##### D10F0x04 Status/Command

| Bits  | Description                                                                                                                                                                                   |

| 2 | <b>BusMaster: Bus Master.</b> Read-write. Reset: 0. 0=Disable the device from generating PCI accesses. 1=Allow the device to behave as a bus master.                                                                                                              |
| 1 | <b>MemorySpaceAccesses: Memory Space Accesses.</b> Read-write. Reset: 0. 0=Disable the device response. 1=Allow the device to respond to Memory Space accesses.                                                                                                   |
| 0 | <b>IOSpaceAccesses: IO Space Accesses.</b> Value: 0. 0=IO accesses targeting this device are not accepted.                                                                                                                                                        |

#### D10F0x08 Revision ID / Class Code

| Bits  | Description                                                                                                                                                   |
|-------|---------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31:24 | <b>BaseClass: Base Class.</b> Read-only. Reset: Ch. Base Class. Serial Bus Controller.                                                                        |
| 23:16 | <b>SubClass: Sub Class.</b> Read-only. Reset: 3h. Sub Class. Universal Serial Bus Host Controller.                                                            |
| 15:8  | <b>ProgrammingInterface: Programming Interface.</b> Read-only. Reset: 30h. Programming Interface. USB 3.0 Host Controller that conforms to xHC specification. |
| 7:0   | <b>RevisionID.</b> Read-only. IF (RevA0) THEN Reset: 00h. ELSEIF (RevA1) THEN Reset: 01h. ENDIF.                                                              |

#### D10F0x0C Miscellaneous

| Bits  | Description                                                                                                                                                                              |
|-------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31:24 | <b>Bist.</b> Value: 0. 00h=BIST is not supported.                                                                                                                                        |
| 23:16 | <b>HeaderType: Header Type.</b> Value: 00h. 00h=The device does not have multiple functions. Bit 7 of this field can be modified through <a href="#">XHCL_PmX28</a> [PciHeaderTypeBit7]. |
| 15:8  | <b>LatencyTimer: Latency Timer.</b> Value: 0.                                                                                                                                            |
| 7:0   | <b>CacheLineSize: Cache Line Size.</b> Read-write. Reset: 0. This read/write field specifies the system cache line size in units of doublewords and must be initialized to 00h.          |

**D10F0x10 Bar 0**

| Bits | Description                                                                                                                                                       |
|------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31:4 | <b>Bar0</b> . Read-write. Reset: 0. Specifies Base Address [31:4]. See <a href="#">3.27.4.3.2 [xHCI Memory Mapped IO Configuration Registers]</a> .               |
| 3    | <b>PM: Prefetch memory</b> . Value: 0. 0=Indicates that there is no support for prefetchable memory.                                                              |
| 2:1  | <b>Tp: Type</b> . Value: 10b. 10b=64 bit address.                                                                                                                 |
| 0    | <b>Ind: Indicator</b> . Value: 0. 0=Indicates that the operational registers of the device are mapped into memory space of the main memory of the PC host system. |

**D10F0x14 Bar 1**

| Bits | Description                                                                                                                                                             |
|------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31:0 | <b>Bar1: Base Address High</b> . Read-write. Reset: 0. Specifies Base Address [63:32]. See <a href="#">3.27.4.3.2 [xHCI Memory Mapped IO Configuration Registers]</a> . |

**D10F0x2C Subsystem Vendor ID / Subsystem ID**

| Bits  | Description                                                                                                                                                                         |
|-------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31:16 | <b>SubsystemID: Subsystem ID</b> . Read-only. Reset: 7814h. Subsystem ID. Programmable through PCI/JTAG path and locked by (D10F0x4C_x04[CfgWriteOnceLock]==1).                     |
| 15:0  | <b>SubsystemVendorID: Subsystem Vendor ID</b> . Read-only. Reset: 1022h. Subsystem Vendor ID. Programmable through PCI/JTAG path and locked by (D10F0x4C_x04[CfgWriteOnceLock]==1). |

**D10F0x34 Capability Pointer**

| Bits | Description                                                                                                          |
|------|----------------------------------------------------------------------------------------------------------------------|
| 7:0  | <b>CapabilityPointer: Capability Pointer</b> . Read-only. Reset: 50h. Address of the 1st element of capability link. |

**D10F0x3C Interrupt Line**

| Bits  | Description                                                                                                                                                                                                                                                                                                             |
|-------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31:16 | Reserved.                                                                                                                                                                                                                                                                                                               |
| 15:8  | <b>InterruptPin: Interrupt Pin</b> . Read-only. Reset: 1. Specifies which interrupt pin the device (or device function) uses. A value of 1 corresponds to INTA#.                                                                                                                                                        |
| 7:0   | <b>InterruptLine: Interrupt Line</b> . Read-write. Reset: 0. Specifies which input of the system interrupt controller(s) the device's interrupt pin is connected to. The device itself does not use this value; rather it is used by device drivers and operating systems to determine priority and vector information. |

**D10F0x40 IDP Index Register**

| Bits  | Description                                                                                                                                                                                     |
|-------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31:13 | Reserved.                                                                                                                                                                                       |
| 12:2  | <b>IDPIndex: IDP Index.</b> Read-only. Reset: 0. This register selects the doubleword offset of the memory mapped register to be accessed. All register accesses are at doubleword granularity. |
| 1:0   | Reserved.                                                                                                                                                                                       |

**D10F0x44 IDP Data Register**

| Bits | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
|------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31:0 | <b>IDPData: IDP Data.</b> Read-only. Reset: 0. Specifies the data read from or written to the memory mapped register pointed to by <a href="#">D10F0x40</a> . A physical register is not actually implemented as the data is actually stored in the memory mapped registers. The default value is the same as the default value of the register pointed to by <a href="#">D10F0x40</a> . <a href="#">D10F0x4C_x04[CfgWriteOnceLock]</a> ==1 is used to prevent use of indirect data register. |

**D10F0x48 Indirect PCI Index Register**

| Bits        | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |             |                   |  |             |                   |             |                   |     |                                    |     |          |     |                                   |     |          |

|------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31:0 | <b>IndirectPCIData: Indirect PCI Data.</b> Read-write. Reset: 0. Specifies the data written to/read from the PCI indirect space register pointed to by <a href="#">D10F0x48</a> . A physical register is not actually implemented as the data is actually stored in the PCI indirect space registers. The default value is the same as the default value of the register pointed to by <a href="#">D10F0x48</a> . |

**3.26.4.3.1.1 USB 3.0 125 MHz PCI Indirect Space**

These registers are indirectly accessed through [D10F0x48](#) and [D10F0x4C](#).

**D10F0x4C\_x08 Port Disable Write Once**

| 24:22 | <b>AuxCurrent.</b> Read-only. Reset: 0. Specifies the 3.3 V auxiliary current requirements for the PCI function. Since <a href="#">D10F0x54[Data]</a> is implemented by this function, reads of this field must return a value of 000b; <a href="#">D10F0x54[Data]</a> takes precedence over this field for 3.3 V auxiliary current requirement reporting. |
| 21    | <b>DSI: Device Specific Initialization.</b> Read-only. Reset: 0. This bit indicates whether special initialization of this function is required (beyond the standard PCI configuration header) before the generic class device driver is able to use it.                                                                                                   |
| 20    | Reserved.                                                                                                                                                                                                                                                                                                                                                  |
| 19    | <b>PmeClock: PME clock.</b> Read-only. Reset: 0. 0=Indicates that no PCI clock is required for the function to generate PME#.                                                                                                                                                                                                                              |
| 18:16 | <b>Version.</b> Read-only. Reset: 011b. 011b=Indicates that this function complies with Revision 1.2 of the PCI Power Management Interface Specification.                                                                                                                                                                                                  |
| 15:8  | <b>NextItemPointer: Next Item Pointer.</b> Read-only. Reset: 70h. Points to the location of next item in the function's capability list.                                                                                                                                                                                                                   |
| 7:0   | <b>CapId.</b> Read-only. Reset: 1. The linked list item is for PCI Power Management.                                                                                                                                                                                                                                                                       |

#### D10F0x54 PME Control / Status

| Bits  | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
|-------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31:24 | <b>Data.</b> Read-only. Reset: 0. Reports the state dependent data requested by <a href="#">D10F0x54[DataSelect]</a> . The value of this field is scaled by <a href="#">D10F0x54[DataScale]</a> .                                                                                                                                                                                                                                                                       |
| 23:16 | Reserved.                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| 15    | <b>PmeStatus.</b> Read; set-by-hardware; write-1-to-clear. Cold reset: 0. BIOS: See <a href="#">2.15.2.13</a> . 1=The PME# signal is asserted, which is independent of PmeEn. 0=PME# is de-asserted. This bit defaults to 0 if the function does not support PME# generation from D3cold. If the function supports PME# from D3cold, then this bit is sticky and must be explicitly cleared by the operating system each time the operating system is initially loaded. |
| 14:13 | <b>DataScale.</b> Read-only. Reset: 0. Indicates the scaling factor to be used when interpreting the value of <a href="#">D10F0x54[Data]</a> . The value and meaning of this field will vary depending on which data value has been selected by <a href="#">D10F0x54[DataSelect]</a> .                                                                                                                                                                                  |
| 12:9  | <b>DataSelect.</b> Read-only. Reset: 0. Selects which data is to be reported through <a href="#">D10F0x54[Data]</a> and <a href="#">D10F0x54[DataScale]</a> .                                                                                                                                                                                                                                                                                                           |
| 8     | <b>PmeEn.</b> Read-write. Cold reset: 0. 1=Enable the function to assert PME# if PmeStatus=1. 0=PME# assertion is disabled. This bit defaults to 0 if the function does not support PME# generation from D3cold. If the function supports PME# from D3cold, then this bit is sticky and must be explicitly cleared by the operating system each time the operating system is initially loaded.                                                                          |

| 3           | <p><b>NoSoftReset.</b> Read-only. Reset: 1. 1=Upon transitioning from D3hot to D0 because of PowerState, devices do not perform an internal reset ; Configuration context is preserved; No additional operating system intervention is required to preserve configuration context beyond writing the PowerState bits. 0=Upon transitioning from D3hot to D0 via software control of the PowerState bits, devices do perform an internal reset; Configuration context is lost; Full reinitialization sequence is needed to return the device to D0 Initialized.</p> <p>Regardless of this bit, devices that transition from D3hot to D0 by a system or bus segment reset will return to the device state D0 uninitialized with only PME context preserved if PME is supported and enabled. This bit is read-writeable by PCI/JTAG path and AHB path rather than read-only defined in PCI PM 1.2 spec.</p> |             |                   |             |                   |     |    |     |    |     |    |     |       |
| 2           | Reserved.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |             |                   |             |                   |     |    |     |    |     |    |     |       |
| 1:0         | <p><b>PowerState.</b> Read-only. Reset: 0. This field determines the current power state of a function and sets the function into a new power state. When doing FLR, power state will be reset to D0 state immediately when <a href="#">D10F0xA8</a>[InitiateFLR] is set. If software attempts to write an unsupported, optional state to this field, the write operation must be completed normally on the bus; however, the data is discarded and no state change occurs.</p> <table><tr><td><u>Bits</u></td><td><u>Definition</u></td><td><u>Bits</u></td><td><u>Definition</u></td></tr><tr><td>00b</td><td>D0</td><td>10b</td><td>D2</td></tr><tr><td>01b</td><td>D1</td><td>11b</td><td>D3hot</td></tr></table>                                                                                                                                                                                    | <u>Bits</u> | <u>Definition</u> | <u>Bits</u> | <u>Definition</u> | 00b | D0 | 10b | D2 | 01b | D1 | 11b | D3hot |

This bit, in conjunction with other bits, controls sending ERR_COR Messages                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |             |                             |             |                     |    |                            |    |                             |    |                            |    |                             |    |                            |       |          |    |                             |  |  |

## D10F0xC4 Device Capabilities 2

| Bits  | Description |
|-------|-------------|
| 31:12 | Reserved.   |

|      |                                                                                                                                                                                                                                                                                                 |
|------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 11   | <b>LTRMechanismSupported: LTR Mechanism Supported.</b> Read-only. Reset: 1. 1=Latency Tolerance Reporting (LTR) mechanism capability is supported.                                                                                                                                              |
| 10:5 | Reserved.                                                                                                                                                                                                                                                                                       |
| 4    | <b>CompletionTimeoutDisableSupported: Completion Timeout Disable Supported.</b> Read-only. Reset: 1. 1=The Completion Timeout Disable mechanism is supported.                                                                                                                                   |
| 3:0  | <b>CompletionTimeoutRangesSupported: Completion Timeout Ranges Supported.</b> Read-only. Reset: 0. Specifies the Completion Timeout value range that can be programmed into <a href="#">D10F0xC8</a> [CompletionTimeoutValue]. 0=Completion Timeout programmability mechanism is not supported. |

### D10F0xC8 Device Control/Status 2

| Bits  | Description                                                                                                                                                                                                                                                                                   |
|-------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31:11 | Reserved.                                                                                                                                                                                                                                                                                     |
| 10    | <b>LTRMechanismEnable: LTR Mechanism Enable.</b> Read-write. Reset: 0. 1=Enable the Latency Tolerance Reporting (LTR) mechanism.                                                                                                                                                              |
| 9:5   | Reserved.                                                                                                                                                                                                                                                                                     |
| 4     | <b>CompletionTimeoutDisable: Completion Timeout Disable.</b> Read-write. Reset: 0. 1=Disable the Completion Timeout mechanism.                                                                                                                                                                |
| 3:0   | <b>CompletionTimeoutValue: Completion Timeout Value.</b> Read-only. Reset: 0. In device functions that support Completion Timeout programmability, this field allows system software to modify the Completion Timeout value. See <a href="#">D10F0xC4</a> [CompletionTimeoutRangesSupported]. |

### D10F0x100 LTR Extended Capability Header

| Bits  | Description                                                                                                                                     |
|-------|-------------------------------------------------------------------------------------------------------------------------------------------------|
| 31:20 | <b>NextCapabilityOffset: Next Capability Offset.</b> Read-only. Reset: 00h. 00h=End of capability list.                                         |
| 19:16 | <b>CapabilityVersion: Capability Version.</b> Read-only. Reset: 1.                                                                              |
| 15:0  | <b>PCIExpressExtendedCapabilityID: PCI Express Extended Capability ID.</b> Read-only. Reset: 18h. Extended Capability ID for Latency Tolerance. |

### D10F0x104 Max Latency

| Bits  | Description                                                                                                                                                                                                                                                                                  |
|-------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31:29 | Reserved.                                                                                                                                                                                                                                                                                    |
| 28:26 | <b>MaxNoSnoopLatencyScale: Max No-Snoop Latency Scale.</b> Read-only. Reset: 0. This register provides a scale for the value contained within MaxNoSnoopLatencyValue. Encoding is the same as the Latency Scale fields in the LTR Message.                                                   |
| 25:16 | <b>MaxNoSnoopLatencyValue: Max No-Snoop Latency Value.</b> Read-only. Reset: 0. Along with MaxNoSnoopLatencyScale, this register specifies the maximum no-snoop latency that a device is permitted to request. Software should set this to the platform's maximum supported latency or less. |
| 15:13 | Reserved.                                                                                                                                                                                                                                                                                    |

|       |                                                                                                                                                                                                                                                                                       |
|-------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 12:10 | <b>MaxSnoopLatencyScale: Max Snoop Latency Scale.</b> Read-only. Reset: 0. This register provides a scale for the value contained within MaxSnoop LatencyValue. Encoding is the same as the Latency Scale fields in the LTR Message.                                                  |
| 9:0   | <b>MaxSnoopLatencyValue: Max Snoop Latency Value.</b> Read-only. Reset: 0. Along with MaxSnoopLatencyScale, this register specifies the maximum no-snoop latency that a device is permitted to request. Software should set this to the platform's maximum supported latency or less. |

### 3.26.4.3.1.3 USB xHCI Capability Registers (XHCI\_CAP)

The base address of the xHCI Capability register space is specified by {D10F0x14[Bar1], D10F0x10[Bar0], 0h}.

#### **XHCI\_CAPx02 HC Interface Version**

| Bits | Description                                                                                                                                                                                                                                                                                                                                                                                                                 |
|------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 15:0 | <b>HCIVersion: Host Controller Interface Version Number.</b> Read-only. Reset: 96h. Contains a BCD encoding of the xHCI specification revision number supported by this host controller. The most significant byte of this register represents a major revision and the least significant byte is the minor revision. e.g. 0100h corresponds to xHCI version 1.0. Writing to XHCI_PMx30[HCIVersion10En] updates this field. |

### 3.26.4.3.2 xHCI Power Management Registers

xHCI power management registers are accessed through the AcpiMmio region, which can be memory mapped or IO mapped. They range from PMx24[AcpiMmioAddr]+1C00h to PMx24[AcpiMmioAddr]+1CFFh. See PMx24 [AcpiMmioEn]. These registers reside in USB 3.0 and can hold their values during S3 or S5 state if the xHC host is programmed into D3 state before entering into S3/S5 state.

| 31:8 | Reserved.                                                                                                                             |
| 7:0  | <b>MsiMsgAddrHi: MSI message address.</b> Read-write. This register specifies the upper 8 bits of the MSI address in 64-bit MSI mode. |

#### D14F2x6C MSI Message Data

Reset: 0000\_0000h.

| Bits  | Description                                                                                                                                                       |
|-------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31:16 | Reserved.                                                                                                                                                         |
| 15:0  | <b>MsiData: MSI message data.</b> Read-write. This register specifies lower 16 bits of data for the MSI memory write transaction. The upper 16 bits are always 0. |

#### D14F2x70 Advanced Features Capability

| Bits  | Description                                                                                                                                                                |
|-------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31:26 | Reserved.                                                                                                                                                                  |
| 25    | <b>TPCapabilities.</b> Read-only. IF (D14F2x44[EnAFCap]==1) THEN Reset: 1. ELSE Reset: 0. ENDIF. 1=Support for Transactions Pending. See <a href="#">Table 81</a> .        |
| 24    | <b>FLRCapabilities.</b> Read-only. IF (D14F2x44[EnAFCap]==1) THEN Reset: 1. ELSE Reset: 0. ENDIF. 1=Support for Function Level Reset (FLR). See <a href="#">Table 81</a> . |
| 23:16 | <b>AFLength.</b> Read-only. IF (D14F2x44[EnAFCap]==1) THEN Reset: 06h. ELSE Reset: 00h. ENDIF. Indicates AF Structure Length (bytes). See <a href="#">Table 81</a> .       |

|      |                                                                                                                                                                                         |
|------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 15:8 | <b>NextPtr: next pointer.</b> Read-only. Reset: 00h. 00h=This the end of the linked list of capability structures. See <a href="#">Table 81</a> .                                       |
| 7:0  | <b>AFCapID: capability ID.</b> Read-only. IF (D14F2x44[EnAFCap]==1) THEN Reset: 13h. ELSE Reset: 00h. ENDIF. 13h=Indicates Advanced Features Capability. See <a href="#">Table 81</a> . |

#### D14F2x74 Advanced Features Control and Status

| Bits | Description                                                                                                                                                                                                                                                                                                                  |
|------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31:9 | Reserved.                                                                                                                                                                                                                                                                                                                    |
| 8    | <b>TransactionPending.</b> Read-only; updated-by-hardware. Reset: 0. 1=Indicates that the function has issued one or more non-posted transactions which have not been completed including non-posted transactions that a target has terminated with retry. 0=Indicates that all non-posted transactions have been completed. |
| 7:1  | Reserved.                                                                                                                                                                                                                                                                                                                    |
| 0    | <b>InitiateFLR.</b> RAZ; write-1-only; cleared-when-done. Reset: 0. A write of 1 initiates Function Level Reset. FLR requirements are defined in the PCI Express Base Specification. Registers and state information that do not apply to conventional PCI are exempt from the FLR requirements given there.                 |

### 3.26.6 Secure Digital (SD) Controller

#### 3.26.6.1 Device 14h Function 7 Configuration Registers (SD)

See 3.1 [Register Descriptions and Mnemonics] for a description of the register naming convention. See 2.7 [Configuration Space] for details about how to access this space.

##### D14F7x00 Device/Vendor ID

| Bits  | Description                                                                                     |
|-------|-------------------------------------------------------------------------------------------------|
| 31:16 | <b>DeviceID: Device ID.</b> Value: 7813h.                                                       |
| 15:0  | <b>VendorID: Vendor ID.</b> Value: 1022h. Specifies a unique 16-bit value assigned to a vendor. |

##### D14F7x04 Status/Command

| Bits  | Description                                                                                                                                                                                                                         |
|-------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31    | <b>DetectedParityError: Detected Parity Error.</b> Read; updated-by-hardware; write-1-to-clear. Reset: 0. 1=The FCH detects a parity error.                                                                                         |
| 30    | <b>SignaledSystemError: Signaled System Error.</b> Read; updated-by-hardware; write-1-to-clear. Reset: 0. SERR# status. 1=The FCH detects a PCI address parity error.                                                               |
